Introduction

As part of official trips made to China in the 1960s, visitors were taken to the Institute of Nationalities in Beijing, the predecessor to today's Minzu University of China (中央民族大学; MUC hereafter), whose mission is to promote research and education for and about China's "ethnic groups". The Chinese word *Minzu* (民族), which can be translated by means of different words in English as we shall explain, replaced that of *nationalities* in the name of the institution, since it is ambiguous in English. Minzu refers to the many and varied "ethnic groups" that compose China, of which the rest of the world knows very little, except for some of the groups which have been highly discussed in "Western" media in the 2020s (e.g. Uighurs in Northwest China). Most visitors to China in the 1960s mentioned their visit to the institution in their memoirs. This is the case of former Canadian premier Pierre Trudeau (1919–2000) who, during his visit to what he refers to as the Institute of Minorities, explained (Trudeau and Hébert, 1967: 48):

It is clear, too, that, among all the students in the Institute of Minorities, the most important, the best prepared, and the most senior are those who are enrolled in the political division and who aspire to become high officials of the Party and of the State when they return to their minorities some day. (At present the minorities provide only four per cent of the members of the Chinese Communist Party.) All the same, the Institute eagerly welcomes those who only wish to become musicians, poets, or dancers. And, far from assimilating these minorities as much as possible (some of them consist of fewer than five hundred people), the powerful Chinese State does all it can to preserve their national characteristics, and notably their languages.

It is asserted that this visit inspired Trudeau to engage with multicultural politics back in Canada (Qian, 2013: 54). Today a visit to MUC will also surprise the neophyte: the institution welcomes every year thousands of students from around the country who might speak languages other than the common language of China (Putonghua, often referred to as Mandarin), and share different worldviews and cultures (see Sude et al., 2020). This diversity is also omnipresent in China, although not so obvious to the untrained eyes. For example, strolling through the Gugong (故宫, i.e. the "Forbidden City" in Beijing), one can see old signs in both Chinese and Manchu (an East Asian Tungusic language from Manchuria in Northeast China) above the Gates and buildings. Every Chinese citizen can see the words "People's Bank of China" in Chinese and in four of China's Minzu languages (Mongol, Tibetan, Uighur and Zhuang) on banknotes in their pockets.

In this chapter we use the notion of Minzu to describe, discuss and problematize the situation of diversity in China, especially in relation to education. This chapter was written during the 2020–2021 pandemic, which was accompanied by many anti-Chinese sentiments in many parts of the world, with discussions about "Chinese minorities" included. However we often felt that critiques of the ways the Chinese are "dealing" with diversity were biased and misinformed. As specialists of interculturality and plurilingualism in education, we feel that we all need to listen to each other and to learn with each other. So-called Western diversity education (different forms of multicultural, intercultural, transcultural and even global education) is far from perfect and has not always proved to be successful. We are not claiming in what follows that Minzu education is a flawless solution or that it offers one-size-fits all recipe. Like all other educational perspectives, it has some "good" and "challenging" aspects. But we argue that by looking into it we can start reflecting on our own ways of "doing" diversity in education. This chapter was thus written with an open mind and it should be read with the same.

Preliminary notes: a short introduction to Chinese education to contextualize Minzu

It is fair to say that Chinese education is largely unknown in other parts of the world, although it has the largest education system in the world with around 10 million students taking the end of high school leaving certificate per year (named *gaokao*, 高考—approximately the entire population of the Nordic country of Sweden).

Often exclusively stereotyped in the media and in some research (Zhao, 2015) for being stressful, competitive, unfair and regimented with 15 million teachers, 300 million students in over 500,000 schools, Chinese education is far from a monolith.

As a reminder China has a population of over one billion, around 17 million newly-born every year, with a territory of about 9 million square kilometers. Just to get a sense of this let's take some examples: the distance between Harbin in the north of the country to Hong Kong is nearly 3000 km and flying time is about 5 h; the distance between Shanghai (East of China) and Kashgar (Westernmost city in China) is 5000 km and takes about 9 h. When we talk of China it is also important to mention the rural-urban divide, with approximately 50% of the population living in both. Up until recently most Chinese families followed the one-child policy—there were exceptions such as families living in the countryside and some Minzu groups—but in 2021, due to the aging population and labor shortage, the three-child policy was implemented.

Since 1986 education has been compulsory and free for 9 years (primary grades 1–6 and junior secondary grades 7–9) and 99% of all school-age children receive these 9 years. It is important to note that in China education is run by the state but decentralized to county-level governments. Pre-school, senior secondary and higher education are neither compulsory nor free, which can represent an economic burden for families since the state only supports very poor students. Early childhood education and care, which is highly privatized, has a small enrollment rate of 10%. Senior secondary education, to which 95% of junior secondary students continue, is divided into general and vocational secondary schools. About 40% of secondary students continue to higher education, a level of education which is very diverse and complex, with different kinds of institutions with varying reputation. Some universities such as Tsinghua and Peking University in Beijing are highly competitive, and are the only ones that can compete with top US universities in most Chinese families' dream of a perfect education and future career path. Interestingly, China is increasingly attracting a large number of international students in higher education (about half a million students per year pre-COVID-19).

For a big country like China, educational equality and equity are a priority. Narrowing the urban-rural gap and regional differences in terms of economic development is important. In rural areas programs such as the Rural Primary and Secondary Boarding Schools Project entitling students to stay in modern dormitories and the Comprehensive Improvement of the Basic School Conditions for Schools at Poor and Underdeveloped Areas, have been implemented for many years. The Special Teaching Post Plan for Rural School aims to attract teachers from urban contexts to teach in rural areas through excellent remuneration and benefits. Finally, long-distance education programs for rural primary and secondary schools have been established (see: Gu et al., 2017; Xue and Li, 2021).

In this chapter, we explore a perspective from Chinese education that has not been discussed in international research. China is a unitary multiethnic state, which means that among its over 1 billion inhabitants, individuals are classified according to different “Ethnic” Minzu groups—56 in total (for instance: Dai, Manchu, Tibetan, Uighur, Zhuang). The labeling of these Minzu groups is the product of a political classification project started in China in 1953 and finished in 1990. We note that different terms have been used in English to refer to these different groups: *ethnic minorities*, *minority groups*, *non-Han peoples*, *local peoples*, *nationalities*, *nationality groups*. In this chapter we use the Chinese term *Minzu* as it avoids misperceptions and inadequate connotations contained in words like *ethnicity*, *minority*, *nationality* in English and other languages, which can be politically marked differently in various parts of the world. We find this perspective to be interesting to unthink and rethink global engagement with languages and literacies in education.

Minzu as a complement to reflecting on languages and literacies in education

Current critiques of the various fields of diversity in education note that theories, methods and practices tend to be overly Euro-/Western-centric and reproduce unequal knowledge power relations (Amsler et al., 2020; Dervin and Jacobsson, 2022). Although diversity education is meant to help people think “otherwise”, try to open up to other ways of reflecting and being, and question the current knowledge and practices that are based on overtly dominating ideologies, what the fields often do is to impose ways of thinking about diversity and interculturality that tend to ignore the diverse ways of thinking about and “doing” them around the world.

A study by Peng et al. (2020) notes that the most quoted scholars in the field of interculturality in education are US- or UK-based, white and English speakers. For a field that strives to discuss and address the position of diverse individuals in education and beyond, this limits the spheres of intellectual engagement with, for instance, issues of equality-equity, social justice and encounters beyond borders. Looking at the list of dominating voices identified by Peng et al. (2020), one cannot help noticing that these Western scholars: (1) use similar concepts and notions in English, without questioning systematically their potential geopolitical and multilingual meanings or their “social lives” (e.g. *culture*, *community*, *respect*, *tolerance*, etc.); (2) emphasize cultural difference over similarity; (3) (somewhat naively) urge people to avoid conflicts and misunderstandings; (4) see diversity negotiations as something linear rather than complex and unstable; and finally, (5) avoid discussing economic, socio-political and ethical elements openly when dealing with interculturality (see Dervin, 2016; Dervin and Simpson, 2021).

Some localized forms of alternative, complementary and companion education have been identified in the literature, such as *interculturalidad* in South America, *interculturalité* in France, *tabunka kyōsei* (“multiculturalism and coexistence”) in Japan. Minzu, as a perspective from China, has not been discussed in international research on interculturality and diversity. The influence from outside China on the way Minzus have been classified and discussed in the 20th century is noted by Guo (2020: 17), who asserts: “[...] when foreign words and ideologies such as race, ethnicity, nation, nationalism, civilization and society were introduced into China, scholars at that time were struggling to understand these terms and how to relate them to the Chinese context”. The fact that translations of the word Minzu in English and other languages are multiform and somewhat confusing seems to derive from this mix of often a-contextualized ideologies that have penetrated the Chinese field of thought about Minzu since the early 20th Century.

To explain briefly the idea of Minzu we could say that it symbolizes a certain view of the heterogeneity of the Chinese nation and of the interaction between different groups which together form an entity called the *People's Republic of China*. As much as European nation-states were categorized as they stand today, through (re-)negotiation of (national) identities, (national) languages and (national) symbols, Minzus are the results of historical interactions between different kinds of peoples coming together. However, we note that, unlike many other places in the world, discussions of diversity and interculturality, via Minzu, are central in internal political and economic discourses in China and engagement with education.

We repeat: Getting acquainted with Chinese ways of discoursing about diversity, through Minzu, does not mean suggesting that we should copy and/or implement them in our respective contexts. Of course, there might be ideas that deserve being considered as inspiration, but it is up to the reader to decide what to do with them. We see considerations of Minzu as a way of allowing ourselves to reflect on how we *see* and *do* languages and literacies but also diversity and interculturality in our respective parts of the world—like looking in a mirror—taking stock of achievements, challenges and potential changes.

Minzu as a complex notion

Throughout its history, China witnessed interactions between different Minzu groups. Until 1911, China was ruled by the Manchu Minzu from Northeastern China (the last emperor Puyi from the 1987 film entitled *The Last Emperor* by Bertolucci was a member of the Manchu Minzu). According to Leibold (2016), it is around that time that the notion of Minzu appeared, influenced by Japan. As such, a Qing Dynasty scholar, Liang Qichao (梁启超, 1873–1929), is often reported as having translated the Japanese term *minzoku* (民族) into Minzu in the late 19th century, making the notion part of the discourse on the Chinese national state-building and of the nation-state. The Chinese word Minzu is composed of *min* (民) for “folk or common people” and *zu* (族) for “consanguinity or lineage”.

56 Minzu group identities and memberships are officially recognized by the Chinese State today. The Han majority represents about 91.5% of the population while the other 55 Minzu groups 8.5% (Zang, 2016: 1). In many cases the latter are often viewed as socio-economically, culturally and ethnically different from majority Han Chinese, but not necessarily “poorer” or “less educated” as is often wrongly suggested by some Chinese and foreign scholars. Minzu status appears on people’s identity documents and depends on their parents’ own status (e.g. Chinese Han, Chinese Korean, Chinese Uighur, etc.). Note that the idea of Minzu only applies to Mainland China and that in other parts of China such as Hong Kong, the concept of “ethnicity” refers to other categories, i.e. people from outside China, who speak a language other than Chinese/Cantonese (Pakistanis, Filipinos, etc.).

China has been described as consisting of different Minzu groups that interact with each other and have been integrated into the Chinese nation during its history. Different Minzu groups are scattered in different territories of the country, with many concentrated on border regions with, for instance, Kazakhstan, Korea, Mongolia, and Russia. There are also five provincial-level ethnic autonomous regions: Inner Mongolia Autonomous Region, Xinjiang Uygur Autonomous Region, Guangxi Zhuang Autonomous Region, Ningxia Hui Autonomous Region and Tibet Autonomous Region (Sude et al., 2020). We should bear in mind with Wang and Du (2018) that “ethnic minorities [Minzu] are not a group of homogenous people. The differences within ethnic minorities should not be ignored as well”. Many of the groups that compose these different areas share languages, worldviews and cultural aspects with groups on the other side of the borders. In interviews that we conducted with international students based at MUC, some students note these similarities. For example a student from Laos explained that his own language group (Laotian speakers) and the Bouyei language spoken by some Chinese Minzus in the Southern Guizhou Province of China are both Kra-Dai languages, tonal languages spoken in Southeast Asia, Southern China and Northeast India with around 93 million speakers, which are not necessarily unintelligible.

We also note that some Minzu minorities have different first languages on top of Mandarin Chinese, the common language of Mainland China and that some of their languages were divided politically at some point but might be very similar to other Minzu languages. For instance, we conducted a research interview with a specialist of the Bouyei who live in the South of China and number approximately 2.5 million people (Dervin and Yuan, 2021). When asked what language the Bouyei speak, the scholar discusses its similarities/differences and shared un/intelligibility with Zhuang from another Minzu. Zhuang is from the Tai family including Thai and Lao:

Excerpt 1

I(interviewer): If one person speaks Zhuang language, how much can you understand?

S(specialist): It depends on what region the person is from.

I: What if they are from Wuming [located in the capital of Guangxi Zhuang Autonomous Region of South China]?

S: I can't understand the Zhuang language in Wuming area, because it is very different from Bouyei language. But I can understand the Zhuang words of areas like Tianlin [County in the west of Guangxi] and so on.

I: How much can you understand? 50%?

S: I can understand 80%.

I: Can you understand 80%? Why?

S: Because the Zhuang language in these areas has a lot of the same vocabulary as Bouyei.

Zhuang is in fact a complex set of more than 12 languages spoken in the South of China, which are not mutually intelligible (Handel, 2019). This shows that the borders between Minzus are not always clear-cut and that complexity and hybridity seem to be strong components of what Minzus are from cultural and linguistic perspectives.

According to the Constitution and Law of the People's Republic of China on the Standard Spoken and Written Chinese Language, all Minzus are entitled to use and develop their own spoken and written languages (2004: Article 4): "All nationalities have the freedom to use and develop their own spoken and written languages and to preserve or reform their own folkways and customs." For instance, in Xinjiang, 10 different languages are used in administration, broadcasting and television, education, legislation and publishing (China Daily, June 30, 2019). It is necessary then to bear in mind that a Chinese person answering the question *what is your mother tongue?* might in fact not reveal their "real" mother tongue or the fact that they are bilingual from birth since many speak other languages as first languages (e.g. Mongolian, Korean, Tibetan, etc.). Instead, they might just mention Mandarin Chinese as their own mother tongue. Mandarin Chinese is the common national language of Mainland China that serves as a lingua franca and is widely used in education.

The notion of Minzu is thus much more complex than the mere naming of different "ethnic" and linguistic groups in China. For Zhao (2014: 31), when we try to express the idea of Minzu in English, "irrespective of which concept of Minzu we employ or which standpoint we take, we are only exchanging one Western model for another, without ever finding a way of identifying and expressing our own Chinese uniqueness".

Minzu as a political-economic and/or cultural-linguistic notion?

Politically, it was the Communist Party of China that made officially the country as a multi-Minzu and unified nation. The identification project, which took many decades, officialized Minzu identities and memberships. What is more, Zhang and Chen (2014: 400) explain that the 1950s marked "the establishment of Autonomous Regions for concentrated ethnic populations, the coexistence of an ethnic language school system and a Mandarin school system as options for ethnic students to choose from, and preferential treatments in minority students' access to college". All these were meant to promote cultural diversity, reforms and regional economic development as well as bridging between "majority" Han and other Minzus. Preferential treatment and policy privileges were widely made available for Minzus, in terms of employment, business development, and political representation. As far as education is concerned, remedial programs, preferential admissions into universities and boarding schools for Minzu students are common today.

In terms of research some Chinese scholars from different fields of research have problematized Minzu. This is the case of the anthropologist and sociologist Fei Xiaotong (费孝通, 1910–2005), whose theory on Minzu groups in Chinese history is influential. Fei argues that all the 56 Minzus share an overarching identity which is the result of centuries of cohabitation and interaction, regardless of their differences in terms of language and culture. The anthropologist and sociologist used the phrases "plural unity pattern" and "unified multiethnic state" (中华民族多元一體; Fei, 1988) to describe Minzu relations: Minzus are plural and diverse, yet, they are united by the fact that they form together the Chinese nation. The Chinese nation is thus both culturally pluralistic and

politically unified. For Fei, in order to coexist harmoniously, all Minzus need to be aware of and accept each other's unique characteristics and joint identity. Many Chinese scholars in education but also Chinese policymakers have embraced and implemented Fei's theory (Zhang and Chen, 2014).

However, some Chinese scholars have noted recently problems with the notion of Minzu. As such Zhang (2017) maintains that Minzu can have many different functions in Chinese society, which makes it somewhat polysemic. He argues (Zhang, 2017) that different definitions of Minzu seem to include:

- The United Nations' definition for "ethnic groups"
- The Chinese national definition based on the official categorization following the creation of the Republic of China
- An academic definition for "cultural groups"
- People's identity whereby they self-identify or are identified by others.

Another aspect of current debates is described by the same scholar (2017) who suggests, following Ma (2017), that the overemphasis on ethnic issues to deal with Minzus makes it too broad as it encompasses different elements such as cultural, social, religious but also economic issues (e.g. poverty). Ma (2017) had argued that autonomization of regions and preferential policies to boost certain Minzu groups' economic outlook, have led to the politicization of Minzu groups, which isolates them and creates, at times failed Minzu integration. Zhang and Chen (2014: 405) summarize this problem as follows: "(...) in the attempt to pacify minority groups and enhance social solidarity and national unity, the Chinese authorities had engaged in an active process of establishing, essentializing, and staticising cultural differences between groups". Zhang (2017) thus proposes that a focus on the cultural specificities of Minzu groups while bridging them with others, would ensure smoother relations between representatives of these groups. We note that discussions of culture and Minzus are common in scholarly circles, while linguistic aspects are somewhat left aside or embedded in discourses of "culture".

Minzu education as a mirror for education in other contexts?

It would be wrong to pretend that Minzu education is a label that refers to a unified approach to cultural and linguistic diversity in education in China. In fact, it refers to many and varied formal and informal aspects of Chinese education, related in/directly to Minzu.

As such different models of Minzu education have been identified in the literature. First, some Minzu groups can be educated in their first language in their home provinces, in Mandarin Chinese or in both languages (Leibold and Chen, 2014). Linguistically this means for example that a Mongolian student studying in a bilingual school gets to learn, use and work in three (very) different languages: Mongolian, Mandarin Chinese and English (which is compulsory). Second, three different types of primary and secondary schools are available: mono-ethnic Minzu schools, mixed Minzu schools, and mixed Han/other Minzu schools. Top students from Tibet and Xinjiang can also receive their middle and high school education in Putonghua in other provinces (so-called "inland" education). Leibold (2016) thus argues that China has the world's most extensive regime of minority affirmative action policies or "preferential policies" (优惠政策) in terms of admission to educational institutions and employment in state or public institutions, acknowledging the existence of educational inequality.

It is important to note that in terms of teaching, Minzu education concerns, on the one hand, specific forms of educational approaches, such as meeting the needs of Minzu students through bilingual education in Minzu regions, and Minzu higher education institutions like MUC in Beijing where Minzu cultures and languages are taught; and, on the other hand, education for all, with, for instance, the teaching of aspects of Minzu included in moral and political education in Chinese basic education.

This is confirmed in a review of what Zhang and Chen (2014) call "Chinese Multicultural Education":

- In Chinese citizenship education the centrality of both national and Minzu identities is emphasized. Strengthening all citizens' Chinese national identity (like in most other countries—see for instance the idea of *citizenship education* in Europe) is deemed essential to ensure social cohesion.
- Minority cultural and linguistic teaching is made available to Minzu students who have a first language other than Mandarin Chinese.
- School culture and as many teaching activities as possible should integrate students' cultural and linguistic backgrounds and experiences in basic education all over the country.

Theoretically, there have been attempts at problematizing and conceptualizing Minzu education. However, there is no unified theoretical underpinning of Minzu education in China, apart from the notion of "plurality within unity", which relates Chinese national unity and Minzu diversity. Chinese students tend to experience diversity in terms of language, culture, and sometimes worldviews/religions. Their identity can thus be situated on a continuum of "Chineseness" and "Minzu" (see Yang's (2017) study on different Tibetan students' identification).

Xing (2001: 580–581) is one of the few scholars to have tried to devise an "integrated multicultural education" containing both "plurality within unity" and (American) multicultural education (following American scholars like James Banks). His work was influenced by anthropologist Fei (1988) oft-quoted paper "The Chinese Nation with Multi-ethnic Groups" which contains a macro-theory of the formation and structural characteristics of the Chinese nation. His main analytical element of China as a unified multi-ethnic country is summarized in the phrase 一体多元 (*yiti duoyuan*, *united but pluralistic*). As mentioned earlier,

Fei's theory has been adopted by both education policymakers and scholars in China under the label "unified pluralist education" (多元一体教育, *duoyuan yiti jiaoyu*). Through this aspect Minzu students learn about their own Minzu's origins, history of formation and development while reflecting on the fact that their Minzu is interrelated with other Chinese Minzus through a common sense of national belongingness and unity.

Teng's (2010) own approach to "integrated multicultural education" was also directly inspired by Fei's work. In 2012 Teng described his approach as follows: "the education of a multi-ethnic country has the function not only to transfer the common human cultural achievements, but also, it should pass on the valued and time-honored cultural traditions of its dominant ethnic group as well as the ethnic minorities." (p. 165) The aims of this approach are to promote common economic development, cultural heritage, cross-cultural communication, the political equality of all Minzu groups, and the ultimate realization of national unity (Teng, 2010). For Teng (2012) all these elements concern all students in all Chinese schools, majority Han as well as other Minzu groups. As such Han students (and teachers) should get to know the languages and cultures of various Minzu groups too (Teng, 2012).

Zhang and Chen (2014) discuss a range of policy initiatives from 1987 onwards that represents a clear shift from education for different Minzu groups to what is referred to as "ethnic solidarity education". This kind of education is now included in moral and patriotic education in primary and middle schools and named "national unity education" (民族团结教育). Several textbooks are used to teach this subject and introduce students to *The Big Chinese Family* (primary school), *Ethnic Basics* (primary School), and *Basics of Ethnic Policy* (middle school).

Interestingly many Chinese scholars have used "American" multicultural education theories and practices to discuss the principles of Minzu education. For instance Zhang and Chen (2014) remark that there are both similarities and differences between diversity education from the "West" (multicultural/intercultural education) and Chinese Minzu perspectives. In terms of differences Zhang and Chen (2014) note that Chinese Minzu education is based on a different policy approach ("Pluralistic Unity of the Chinese Nation" with an emphasis on difference and similarity), and that its concerns have more to do with economic, social and cultural development rather than, for instance, issues of political equality.

As in other countries, national identity is seen as fundamental in Chinese Minzu education to ensure social cohesion and reduce potential Minzu tensions (Qian, 2010). More importantly, Minzu groups in China are indigenous peoples unlike many of the "targeted" populations in "Western" diversity education (e.g. multicultural/intercultural education), who e.g. migrated to the US or Europe. We might want to add that multicultural and intercultural education emerged from specific historical contexts. As such multicultural education was born out of the 1960s civil rights movements while intercultural education out of European decolonization in the 1970s (see Derwin and Jacobsson, 2022). Economic-politically speaking these differ from Chinese Minzu, whose sometimes disadvantaged position is said to derive from "the harsh climate, undesirable geographical conditions and economic underdevelopment in the border land they occupied" (Zhang and Chen, 2014: 403). In the "West", diversity education often relates to situations of education diversity in urban and large city contexts.

How is Minzu education taking place?

Engaging with the literature published in English, we note that there is a lack of an overview of what Minzu education encompasses. Fig. 1 represents an attempt at clarifying what this multifaceted label includes and lists perspectives that concern certain groups of students (e.g. bilingual education) and all Chinese students (e.g. national unity education).

The examples in this figure do not include informal education whereby, for instance, Chinese people learn about other Minzus. For example, in an interview with a Bouyei Minzu specialist (South of China) at MUC, we discussed the idea of the "sworn brothers

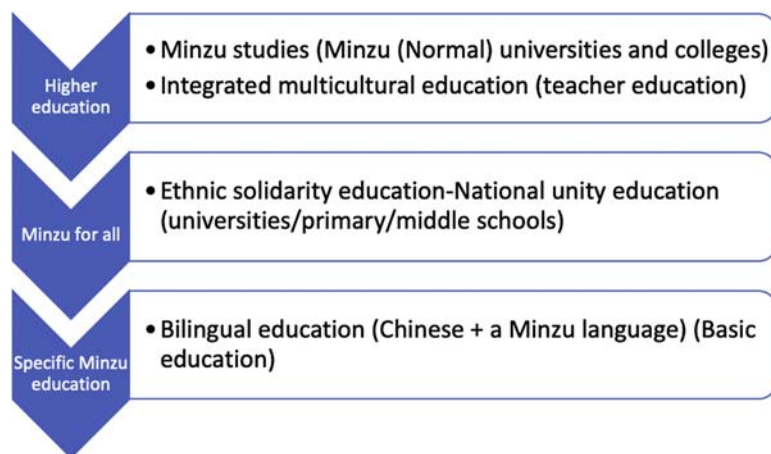

Fig. 1 Layers of Minzu education (examples) (Derwin and Yuan, 2021).

and sisters" tradition (結拜) (Dervin and Yuan, 2021), which creates some form of Godparent relations between people of different Minzus (e.g. Bouyei & Han/Miao). In his study of a Miao Minzu village, Wang (2018: 62) describes what "sworn brother-/sisterhood" consists in: "all sworn brothers come to give a hand for carrying firewood, while the housewife prepares a feast for coming brothers and their wives. They sit around eating, talking, laughing and playing poker until midnight. The gathering makes both cooperation among sworn brothers and progression emotion each other." This habit is qualified as "a basis for Minzu unity" by the Bouyei scholar whom we interviewed, which he confirms by claiming that "This custom would not exist if Minzu groups did not believe in each other". This Minzu inclusiveness from the Bouyei side is also illustrated by the Bouyei scholar's claim that Minzus learn each other's language to be able to interact with each other:

Excerpt 2

We learn the languages of other peoples in order to acquire a life skill of communicating with them. It is not surprising, for example, that Han people living in the Bouyei Minzu region are generally fluent in the Bouyei language, and that Bouyei people can also speak Chinese. In this way, there will be no misunderstandings between different Minzus because of language barriers. When I can speak your Minzu language, there is no barrier between us.

We discuss formal bilingual education in what follows, which plays a central part in Chinese Minzu education. Gao and Ren (2018) maintain that the 55 Minzu minority groups speak over 209 languages (e.g. Mongolian, Tibetan, Uyghur, Zhuang). In the past Chinese scholars have noted that many Minzu students stop learning their Minzu languages because they perceive them as "futile" in the labor market, especially when competing with other students with good Standard Chinese skills (e.g. Zeng, 2014). This has been perceived as counter to the plural unity pattern. This is why Minzu bilingual education has been put into place around the country. According to Zhou (2012) 21 Minzu groups have implemented some form of bilingual education for approximately 6 million Minzu students, whereby they get to learn three languages: their first language (a Minzu language), Chinese and English. Different types of bilingual education are offered in different parts of the country (Mańkowska, 2019): (1) a Minzu language is the main language of instruction from kindergarten to middle school, with Chinese taught as a separate subject; and (2) A Minzu language is used at the start of school education to help non-Chinese speakers easily understand the content. In higher grades, the percentage of Minzu language teaching is reduced, and the Chinese language predominates. It is important to note that thousands of textbooks are available in Minzu languages and consist of direct translations of textbooks published in Chinese.

At the time of writing, in a project that we were running about Science, Technology, Engineering and Mathematics (STEM) education in bilingual and Chinese-speaking schools the Mongolian city of Ordos (鄂尔多斯) (Yuan et al., under review), we discussed with primary school teachers how they negotiated multilingualism. In the Chinese-speaking schools, all teachers (be they Mongolian speakers or not) use exclusively Chinese to teach and may use Mongolian when they speak to individual students. Chinese is the school lingua franca and using other languages during teaching would be considered as discriminating against those who don't speak them. In the bilingual schools, the teachers and students use mostly Mongolian, yet, there are times when Mandarin Chinese is useful for both teachers and students. A technological instructor explained for instance that the review materials for national exams were limited in Mongolian so he had to use material produced in Mandarin Chinese. What is more, some teachers reported using code-switching between Mongolian and Mandarin Chinese for certain words that do not have "accepted" equivalents in Mongolian. The following excerpts are from fieldwork in two different Mongolian bilingual schools:

Excerpt 3

I: Right. Can you give me a specific example from your teaching experience? For example, if you speak to them in Mongolian, they may not understand you and you have to explain it in Chinese.

T: Like "dissolve".

I: Is there a special word for it in Mongolian?

T: Yes. And now most children watch cartoons that say "dissolve". They get it when they read it.

I: Maybe they have seen "dissolve" in cartoons and know what it means, but in Mongolian they may not know.

T: Yeah.

Excerpt 4

T: According to the actual situation of Mongolians, liberal arts, such as politics, history, language, etc., are more in line with the history of the Mongolian people. There are many technological aspects of Mongolian language, such as tractors. The Mongolian people do not have tractors. We still have to use Chinese or English.

To dissolve and *a tractor* are two examples that many teachers mentioned during the interviews.

In terms of teaching STEM, we were also curious about the use of ICT and written Mongolian during our visits to the schools. In China, unlike the country of Mongolia where it is written in Cyrillic, the traditional Mongolian script is used. Derived from the old Uighur alphabet, it is written in vertical lines right across the page. In our interview with a math teacher, he discussed the use of Mongolian in the iPads used in his school:

Excerpt 5

I: Is Mongolian the language of the iPads?

T: Yes. In the western area of China, we have developed a Mongolian software in 2019, and now we can directly use Mongolian for courseware. Originally the words that we write in Mongolian are “upside down”, so we needed to correct the typesetting after writing. Later, we had a training session. A lecturer from the West came to train us. We reported to him about the software problem. After he returned, he upgraded the software. Now writing Mongolian in the software isn’t “upside down” any longer, it is exactly the same as other software we use.

Besides languages, we also note that most teachers wish to pass on certain values that they consider to be specific to Chinese Mongolians to their students, while discussing STEM elements. In the following excerpt, a chemistry teacher makes a reference to the importance and protection of water by Mongolians:

Excerpt 6

I think about it ... Mongolian ... Um ... About the Mongols ... (Long pause) Well, it should be ... a frugal aspect of Mongolian culture. Because we have water in the fourth chapter, water is said to be all around us in that chapter, I just tell the students it’s frugality, and then don’t waste water. Perhaps that’s it.

Although this example might sound anecdotal, the teachers seemed to systematically include such elements in their classrooms and in their teaching. All of them admitted not having been professionally prepared for including these Mongolian Minzu elements or to support the students linguistically but that they “improvised” them for STEM education.

In general, one of the main issues faced by Minzu education is the lack of consistent teacher education and training focusing on Minzu. In autonomous regions of China, around 100 Minzu normal universities, normal colleges, or schools for teacher education and training have been established. Some Minzu universities and colleges located in Minzu areas also offer Minzu teacher education programs. Teacher training centers have been established and Minzu teacher education courses are also widely available in major Normal universities around China such as Beijing Normal University, Central China Normal University, and East China Normal University. These programs are opened to both Han and non-Han students. It is also important to note that inland universities have signed partnerships with universities in Minzu areas to offer assistance in terms of Minzu teacher education and training. For instance, inland experts are sent to Minzu areas to take part in teaching and research programs.

In general, Minzu teacher education and training appears scattered, and somewhat inconsistent. The emphasis appears to be on preparing teachers for specific Minzu groups rather than for mixed groups. What is more it is often unclear who gets trained: Han-majority to work with other Minzus and/or vice versa? Most review articles of Chinese Minzu education include very few references to this specific issue although forms of Minzu teacher education and training have been organized since the founding of the People’s Republic of China (Hawkins, 1978). A few articles have examined teacher education and training for teachers dealing with Minzu issues. For example, Ou and Du (2017)’s article shows that teachers interested in strengthening students’ Minzu identity can have

Fig. 2 Basic values of Minzu education (Dervin and Yuan, 2021).

a positive impact on their academic achievement. In her 2011 review article of a teacher education program in the Xinjiang Uyghur Autonomous Region, Liu proposes that knowledge of “multicultural education” should be added to the curriculum. Finally, in their 2014 paper entitled “Creating a multicultural curriculum in Han-dominant schools: The policy and practice of ethnic solidarity education in China”, Zhang and Chen (2014) look into teachers’ preparedness to implement ethnic solidarity education in a mix of (Minzu/non-Minzu) schools in Beijing. Their findings reveal that the schools incorporated Minzu elements in the school environment, in teaching and extra-curricular activities; however, the scholars note that “they tended to focus on the static cultural artifacts, such as food, music, dance and sports etc., which represented the museum-like knowledge about different ethnic groups, i.e. the so-called ‘living fossil’” (Zhang and Chen, 2014: 412). “Cultural heritage” rather than e.g. fluid and “living” perspectives on cultural complexity was highlighted. Zhang and Chen (2014) also assert that many teachers and school leaders found ethnic solidarity education to be unneeded.

In their extensive literature review of Minzu education from 2000 to 2018, Liu et al. (2020) claim that teacher education and training for Minzu is one of the six important topics in the field. The review seems to confirm that, in general, teacher education in China seems to lack systematic and coherent Minzu perspectives. Some scholars have made suggestions as to how to strengthen this aspect of Minzu teacher preparation: Zhang (2015) emphasizes the importance of critical thinking and creative thinking; Pu and Liu (2017) insist on creating a common sense of belonging by, for instance, teachers and students learning from each other through cultural exchange; and Zheng (2012) suggests that teachers explore the preferred learning styles of Minzu students. Developing multicultural and multilingual teaching strategies is deemed to be an important option. We note again that languages and literacies do not appear to be systematically discussed directly in research on teacher education and training but that they could be embedded in discourses of “culture”.

Conclusions

Real dialogue isn’t about talking to people who believe the same things as you.

Bauman (2016: n.p.).

At the end of this chapter, we note that Minzu education is a complex and yet rich perspective on “internal” diversity, which has been rarely discussed in global scholarship of languages and literacies. Like any approach to diversity in education, Minzu is based on political, scholarly and educational views of “us” and “them”, while trying to create a bridge between these entities. Although there are some similarities in terms of ideologies and practices with “Western” multicultural and/or intercultural education, Minzu education does have its own specificities. Figure 2 summarizes the basic values of Minzu education (Fig. 2):

Although the model might appear linear or hierarchical, all the different components are interrelated. These elements also appear to be overarching in the way multiple involvement with Minzu education has been organized in China. In red we indicate the basic politico-economic values around discussions of Minzu education: *unity in diversity* (i.e. we share similarities at the national level but differences at Minzu group levels), *economic development* (which is considered to be the key to equality among Minzus; see “preferential policies” for certain Minzus as a boost). The green elements indicate the principles of Minzu education observed nationally: *Minzu literacy* (the presence of Minzu representations and discourses in education for all; support for Minzu groups to become aware of their own Minzu specificities and similarities with other Minzus), *multilingualism* (Chinese, Minzu languages for Minzu language speakers and English as a global language) and a *positive attitude to all* (reducing prejudice, awareness and removing negative ideas about different Minzus).

To conclude this overview of Chinese Minzu diversity and education, we would like to renew our advice to examine the way languages and literacies are dealt with in contexts which are rarely discussed in diversity education (see Dervin and Jacobsson, 2022). Entering the world of Minzu requires adopting a different mindset and rethinking the way we use words, understand concepts and notions, but also policies and practices. What we noticed is that although concepts such as *social justice* are not omnipresent in discussions of Minzu in education, other words hint at similar ideologies about language and culture (e.g. the right to access to development).

Introduction

Literacy in foreign languages was introduced into the African continent in the 10th century AD and through the centuries thereafter, Portuguese, Arabic, and English languages assumed prominent roles in the politics of literacy in African countries such as Nigeria. This raised pertinent questions of the role of Indigenous languages in literacy dialectics in Nigeria (Fig. 1). The contentions have continued to generate concerns through the missionary, to colonial, and to post-colonial (contemporary) Nigerian educational experiences and attainment. They have often translated into the debate on which language should be used for education, and the dichotomy between the home language and the school language, with implications for educational achievement premised on the linguistic diversity in Nigeria. In the traditional (Indigenous) Nigerian system of education, the medium was the mother tongue (MT) while oracy was its pivot. In formal Nigerian education, which was introduced by foreigners, English is the primary medium while literacy is its pivot.

In the rest of this chapter, six key developments will be examined. First, we will analyze Indigenous Nigerian education before foreign systems of education were introduced into Nigeria. We will show how oracy promoted communication among Nigerians and served as the instrument through which Nigerians promoted their culture, science and technology in their various MTs. Second,

Fig. 1 Map of Nigeria representing the 36 states, the Federal Capital Territory, and the Northern and the Southern Regions. Courtesy: Chizoba Ikenwa (nigerianinfopedia@gmail.com), <https://nigerianinfopedia.com.ng/northern-states-in-nigeria/>.

we will examine the impact of formal education on literacy empowerment before the commencement of the Trans-Atlantic slave trade. Third, we will situate literacy in Nigerian education after the abolition of the slave trade. Fourth, we will examine the role politics plays in the literacy enhancement and achievement of Nigerians. Fifth, we will try to summarize the key measures being taken to gestate and birth literacy in Northern Nigeria. Finally, we will suggest a Literacy Enhancement and Achievement Paradigm (LEAP), a teacher/teacher, teacher/learner and learner/learner empirically proven effective literacy instructional and learning model as a paradigm shift in the promotion of literacy.

Nigerian Indigenous education

Nigerian Indigenous education is rooted in antiquity. Fafunwa (2004) has rightly observed that through Nigerian Indigenous education, children were empowered to acquire character, respect for others, physical skills, intellectual capabilities, appreciation of their religion and culture, etc. and oracy centrally underpinned the system of education. Writing on the value of oracy among the Ibos of Nigeria in his celebrated novel, *Things fall apart*, Achebe noted that “Among the Ibo the art of conversation is regarded very highly, and proverbs are the palm-oil with which words are eaten” (p. 6). Indigenous Nigerian education was transmitted orally through a guild system, the home, and a system of apprenticeship. The apprenticeship scheme as a form of entrepreneurship and skills education is still popular in contemporary Nigeria (Fig. 2).

In agriculture and home economics for instance, boys were trained by their fathers or older male members of their home or communities while girls were trained by their mothers or older female members of their communities respectively. In special professions like hunting, medicine, metal work (such as iron smiting, bronze and brass technologies) one had to belong to a guild before one could acquire the knowledge, attitudes, and skills that could make one excel in them. As could be seen in the activities of the Ekpe or Okonko guilds, those who did not belong were not privileged to benefit from the education which the guilds offered. This is because these guilds had their system of reading and writing—their kinds of “literacy”—that were not open to everybody. It is in this

context that we can understand, for instance, the Insibidi writing system developed and used by members of the Ekpe guild in pre-colonial Igbo, Ibibio, and Annang communities of today's South Eastern and South Southern Nigeria. The guilds were also exclusive in other aspects of their activities, including dressing, perception of life, and culinary culture.

The leaders and teachers in their respective fields passed their knowledge, attitudes, and skills through the oral tradition to their students. It was through this mode that the people developed the science and technology that has amazed the world. For instance, the Nok Terra Cotta technology (Jemkur, 2006), which started about 500 BC, is considered one of the best and most sophisticated terra cotta technologies the world has ever practiced. The Terra Cotta art was part of an expansive civilization (National Geographic Society, 2020; Rupp et al., 2008) and its technology was practiced almost in all parts of present-day Nigeria except in the coastal regions of what is now the South-South region. Some historians have argued that the iron smiting technology that flourished in Awka, Anambra State and which provided the bulk of the metal wares used in agriculture, hunting, and warfare in the Gulf of Guinea and the Bight of Biafra is an offshoot of the Nok Terra Cotta technology. Similar arguments have also been postulated that the famous Brass and Bronze (Fig. 3) technologies that flourished in Benin and Ife had their origins from the Nok Terra Cotta technology (Onukaogu, 2008, 2010).

The tragedy of the Nigerian Indigenous education is that it was not allowed to thrive. Just as the Nigerian Indigenous education was refining and repositioning itself in the light of its contact with Arab Islamic education and Western European Christian education—especially in its synchronizing oracy with the emerging literacy, the Trans-Atlantic slave trade set in and further disrupted its development. One can then say that texting in Nigerian Indigenous education was oral while languaging was through the MT of the learner. Oracy however, needs to blend with literacy for education to maximally empower Nigerians for individual and national development. We share Oyedepi's (2007, p. 5) position that oracy has its limitations as stated in the following words:

Oracy was becoming inadequate and inefficient; inadequate because of the multiplicity of cultures that emerged and inefficient because the details in handing over cultures, history, economics and political practices from one generation to another cannot be retained in human memory without written records; hence it is said that when an illiterate dies it is as if a whole library is burnt.

Literacy languaging and texting forms enhance the preservation and transmission of knowledge and sustainable education (Swain, 2006). The political decision of choice of language for literacy has significant implications on the effectiveness of literacy empowerment as demonstrated in latter parts of this chapter.

Situating literacy in Nigerian education

From the 10th to the 15th century AD, there were two sets of foreigners who impacted on the Nigerian Indigenous education, and their impact reshaped the education in the land. It added a new dimension to the oracy through the use of literacy (Onukaogu, 1998, 1999). The first set of foreigners was Arab Islamic missionaries who came in the 10th century AD and were concentrated in Northern Nigeria (Imam, 2012; Oroma and Wosu, 2018). They came primarily to convert the Indigenes to the Islamic faith using Arabic as their medium of communication (Trimingham, 1962; Ogbondah, 2002). The second set was Roman Catholic Jesuit Christian missionaries who came between 1515 and 1580 to the Benin Kingdom where they set up schools and churches (Ogbondah, 2002; Oroma and Wosu, 2018). They introduced Western literacy and emphasized the 3Rs—Reading, Writing, and Arithmetic.

Literacy has meant different things to some members of the Nigerian education orchestra. The Christian missions in the South taught literacy as the 3Rs. To the Christian missionaries, literacy was the pivot of formal education. They ensured that the graduates of their schools and colleges were literate in their MTs and in English. In contrast, the Islamic missions in the North did not teach the 3Rs in the Koranic schools they established. Instead, the Koran was read in Arabic to students who were required to memorize what was read to them. Thus, unlike their Christian school counterparts, the graduates of Koranic schools could neither read/write/compute in their MT nor in Arabic (Ajayi, 1965; Imam, 2012; Oroma and Wosu, 2018).

Generally, literacy is the skill of reading, writing and computation (Oyedemi, 2007). According to Opeyemi (2018, p. 150) “many definitions of literacy focus on the ability to read and write at appropriate levels.” Opeyemi agreed with English and Aers (2008, p. 32) that literacy “is the ability to read and write which makes a person literate, with varying degrees of fluency.”

The Nigerian Educational Research and Development Council (NERDC) holds the view that literacy is a skill. It is this view that informs its mass literacy strategy slogan “each one, teach one.” The Council’s position is based on the assumption that literacy does not require intellectual demands. That is why the Council promotes the assumption that an illiterate person can be taught to be literate by anyone who can read and write. However, some Nigerian scholars contend that “literacy, which used to be traditionally defined as the ability to read, write and calculate ... is man’s capacity to expand his own consciousness in a bid to exercise power over himself, his environment and his society at large” (Adedokun and Kayode, 2019, p. 91).

Literacy has been described as consisting of two models - the autonomous and the ideological models (Onukaogu, 2012; Street, 2006). Street (2006) compared the autonomous and ideological models and indicated that while the autonomous model of literacy presents its underlying cultural and ideological underpinning as neutral and universal; the ideological model challenges this view through research in new literacies that suggest that in practice literacy varies in contexts and cultures.

In the autonomous model, literacy is reading, writing and calculating without any intellectual, cultural and environmental impacts and requirements. In the ideological model, literacy is seen from a much wider perspective where the intellectual and social perspectives of learning, knowledge, attitudes, and skills are essential for its acquisition. Onukaogu observed that literacy has multiple meanings, and he also cited Rassol’s (1999) view that the definitions of literacy change in response to social transitions in history, ideology, or technology.

Indeed, many Nigerian scholars have argued that literacy is a set of knowledge, attitudes and skills for text processing. Ahaotu (2018), Aridegbe and Makinde (2014), Ayodele and Adedokun (2012), Adedokun (2008), and Orisawayi (2006) also shared the view that literacy has expanded in scope and some of them listed new literacies as digital literacy, critical literacy, computer literacy, information literacy, and media literacy. For Ahaotu (2018) literacy includes a variation of the communicative arts, including writing, calculating, cognitive processing of texts, and digital competences through which individuals and societies preserve their modes of interaction, learning, culture, and development. Promoting a synchronicity of the autonomous with the ideological models of literacy, Egbe (2019, pp. 22–23) posited that “literacy is dynamic, contextual and culture specific. This is why ... we speak of not just ‘literacies’ but new literacies given that literacies account for ever expanding dimensions of literacy from its traditional sense.”

UNESCO plays a leading role in global literacy empowerment since 1946 and has described literacy as follows:

Beyond its conventional concept as a set of reading, writing and counting skills, literacy is now understood as a means of identification, understanding, interpretation, creation, and communication in an increasingly digital, text-mediated, information-rich and fast-changing world.

UNESCO (2019, n. p.).

UNESCO’s perspective is that literacy empowers individuals to optimally comprehend the written text in various contexts and enables them to develop their knowledge and potentials to participate more meaningfully in both their community and the wider society. From this perspective, literacy is a critical element of both individual and national development (Ahaotu, 2018).

Both the autonomous and the ideological models of literacy share the view that literacy is a critical factor of human and societal developments. The perspectives of both these exponents and UNESCO’s (2019) definition of literacy may be synthesized into the following key points that are fundamental to literacy:

1. Written texts. Underlying literacy is the written text. The emphasis here is on the distinction between oracy and literacy. In contrast to literacy, oracy does not incorporate elaborate written text. There is no literacy without the written text, and so, it could be contended that without literacy written words have no meaning.

2. Written text diversity. The written text can be on printed materials, and can be reflected on diverse media. This diversity reflects the multiplication of media with the written words on them.
3. Intellectual and processing capabilities. Since the written or printed words have meanings and messages to convey, whoever wants to obtain the meaning or messages in them must have the knowledge, attitudes and skills to process the contexts of the written texts so that the person can identify, understand and interpret their meaning.
4. Synchronicity with oracy. The purposes of using the printed and written materials include creating, communicating and computing meaning. Obviously, oracy, sign language, and Braille may be utilized to share information garnered from the written or printed text given the various contexts in which individuals find themselves.
5. Knowledge, attitudes and skills enhancement. Processing the written text empowers the individual with the ability to identify, understand, interpret, create, communicate and compute meaning. These hallmarks of texting have the potentials of enhancing the knowledge, attitudes and skills of processing and giving information. That is why in the Nigerian situation, literacy is pivotal to the acquisition of knowledge, attitudes and skills in formal and non-formal school systems, where the written text is indispensable to knowledge, attitudes and skills acquisition and storage.

Literacy and the Nigerian language ecology

There are social pressures for the use of English for literacy practices in Nigeria and studies have identified a high demand for English among Nigerians (Ahaotu and Tobiahs, 2020; Famogbiyele, 2017; Egbe, 2014). This is understandable because English is Nigeria's major official language even though there are co-official languages. The NERDC's (2013) *National policy on education* (henceforth, *NPE*, 2013) provided that "Every child shall be taught in the mother tongue or the language of the immediate community for the first 4 years of basic education" (Section 1.8, *NPE*, 2013). The *NPE* stressed that "Government will ensure that the medium of instruction is principally the mother tongue or the language of the immediate community" (Section 2.16) for early childhood care development. However, Section 2.20 of the same document provides that "the medium of instruction in the primary school shall be the language of the environment for the first 3 years in monolingual communities. During this period, English shall be taught as a subject." Thereafter, the transition to an English-medium instruction will start from Primary 4 (P4) and above.

These declarations show degrees of inconsistencies. First, the policy assumes that there are many monolingual communities in Nigeria, which does not reflect the reality of the Nigerian multilingual context. Second, it is assumed that all the teachers have the linguistic competence and training to deliver instruction in the MT or the language of the immediate environment. Third, it is assumed that after 3 years of instruction in English in a second language context, children would have had sufficient proficiency in the language for transition to an all English medium instruction. These policy lacks practical implementation strategies and so, it leaves the classroom teacher in some dilemma; teachers are therefore likely to do what they think is feasible and realistic. Trudell (2018) agreed that there are also internal inconsistencies in the language provisions of the *NPE* and that, "... the *NPE* does not provide a clear, coherent, feasible language-in-education policy ... making them difficult to implement with fidelity" (p. 10). A study by Fadoro (2013) in three Western states of Nigeria found that the provisions of the *NPE* are violated extensively and the inherent inconsistencies of its provisions may have contributed to the violations.

Nigeria is a multilingual country with 526 foreign and local languages (Ethnologue, 2018). Since language remains the vehicle of instruction in the classroom, it is obvious that children with low proficiency in the school language are disadvantaged, especially in multilingual contexts where there is a difference between home language and school language. The importance of the Indigenous languages or MTs as the language of instruction is well documented (Wa Mberia, 2015). However, the high demand of English and its position in Nigeria create some dilemmas for its deployment in literacy. English competes with the three major Indigenous languages in Nigeria (Hausa, Igbo, and Yoruba). English competes with other Nigerian languages that have fewer speakers than the three major ones. English also competes with other foreign languages present in Nigeria. This results in Nigeria being a country with one of the most complex linguistic ecologies globally and increasing the dilemma of the choice of the language of literacy in Nigeria. On a positive note, there is a technical team charged with fashioning out a framework for developing a national language or languages for Nigeria. Bearing in mind that language issues are as volatile and contentious as religious issues in Nigeria, the tensions created by the multiplicity of languages in Nigeria and the inconsistencies identified in the language provisions in the *NPE* have serious implications on literacy development in Nigeria and, very importantly, heighten the politics of literacy in Nigeria as will be shown in subsequent sections of this chapter.

The politics of literacy in Nigeria

Politics, which determines the nature and scope of literacy in Nigeria, is influenced by three principal factors. First, there are the missionaries—Islamic and Christians—who used literacy to achieve their faith winning agenda in the country. Second, there is the Nigerian Federal Government whose literacy agenda is determined by the political party in control of the federal or state governments. Finally, there are the Nigerian scholars who through research and practice are endeavoring to reposition literacy in the Nigerian education system so that proven literacy views and best practices in the world can be adapted in the country.

The impact of missionaries

Impact of Islamic missionaries

We had noted earlier that the Islamic missionaries before and after the era of the Trans-Atlantic slave trade did not teach their students to read in their MTs. Literacy empowerment for critical and creative thinking was not available to the students. Since the students were not taught how to read in their MTs, they lacked the literacy empowerment of linking what they were taught to learn by heart with the day-to-day challenges in their communities. Besides, they were also not taught to read, write and compute in Arabic. If they had been taught to read, write and compute in Arabic, they would have been exposed to the enormous body of information and knowledge in Arabic which had helped to liberate Europe from the Dark Ages and launch the continent into the Renaissance. The Islamic missionaries in Northern Nigeria denied the people literacy empowerment so that they would remain in perpetual submission to their Koranic teachers and the feudal lords the teachers represent. Presently, according to the [UNICEF \(2015\)](#) Demographic Health Survey (DHS), 69% of the 13.2 million out-of-school children today in Nigeria are from the North.

The colonial administration also denied Northern Nigerians literacy empowerment by preventing Christian Missionaries from moving to the North and planting Western European formal education there. [Imam \(2012, p. 183\)](#) cited Fabunmi (2005) to contend that the "British policy of indirect rule restricted the activities of Christian missionaries in the predominantly Muslim Northern protectorate thereby, curtailing the spread of Western education" and also cited Ogunsola (1982) to indicate that this led to considerable education gap between Northern and Southern Nigeria. Obviously, the colonial administration endorsed the literacy disempowerment which the Islamic education posed to the generality of the children of the North. The grants-in-aid which were given to Christian missions to build schools in the South were not given for building and improving the Koranic schools in the North ([Imam, 2012](#)). The majority of children in the North were greatly handicapped; they could not perform literacy activities through their MTs, Arabic, and English. All they could show for their attending formal Koranic schools was the recitation of aspects of the Koran. The colonial administration thus sowed the seed of literacy disparity between the North and the South which today remains the bane of political, social and economic development of Nigeria.

Impact of Christian missionaries

Soon after the slave trade was abolished, Christian Missionaries came back to Nigeria to win converts to their faith and build schools, hospitals and craft centers in the country. Because of the restriction by the colonial administration, they concentrated in Southern Nigeria. By 1842 the first Christian primary school after the abolition of the slave trade was built in Badagry in present day Lagos state.

The formal education that the Christians introduced was anchored on autonomous literacy. The students were taught to read, write and compute in their MT. Because of the ease with which the students could read and write in their MT, and in English, formal education became interesting and very exciting to them. Consequently, there was an explosion in the number of students in formal education. The missionaries could not cope with the demands. They went to the Colonial Office and asked for financial assistance to build more schools. The Colonial Office offered to assist the missionaries only if they used English and not the MTs of the students in their teaching. Since the missionaries desperately needed funds in order to build more schools, they jettisoned the MT for English-medium instruction. This crippled the use of the MT as a medium of instruction in the mission institutions. Many communities in the South built their primary schools and handed them over to the Christian missions to administer.

When the Colonial Administration passed the Macpherson's Constitution in 1951, each of the regions was empowered to appropriate and use funds for education. As a result of this development, Western Nigeria started Universal Primary Education (UPE) in 1955 and Eastern Nigeria in 1957. Northern Nigeria went beyond UPE and gave enticing incentives to Northern children to go to school. However, the dislike in Northern Nigeria for Western formal education prevented the majority of the children from embracing the generous incentives. Enrollment and attendance at schools in the North were comparatively lower than it is in the South.

Since the 1940s the Christian Missions have built first rate primary and secondary schools in the South and the Middle Belt (present North Central States) areas of Nigeria. They also perfected the use of English as a medium of instruction. Their secondary and primary schools compared favorably with the best primary and secondary schools in the British Commonwealth. Literacy taught at the mission schools was now for literal, interpretive, creative, critical, life-long learning across the school curriculum. The graduates of the mission schools excelled in such external examinations as the University of London General Certificate of Education - Ordinary and Advanced Levels - and the University of Cambridge School Certificate Examination. The Colonial Administration established some secondary schools in the country to supplement the efforts of the Christian Missions. There were also few privately owned schools in the South. However, in terms of industry, honesty of purpose and academic excellence, the colonial administration and the few privately owned schools were no match for the mission schools. The literacy for critical, creative, life-long learning, across the school curriculum, and for independent living, which the mission schools had perfected and taught and which the government and private schools emulated, paid off handsomely. This trend continued till 1966 when the civil war broke out in Nigeria. We can say without equivocation that the 1940s-1960s marked the comparative golden age of Nigerian formal education. It was when literacy empowerment, as the pivot of formal education, was at its peak.

The impact of government

It has been shown in this chapter that the colonial government used literacy to socially control, repress the people, and make the people totally submissive to it (see [Stromquist, 2008](#); [Gaff, 1987a,b](#)). It promoted illiteracy in Northern Nigeria and stopped the use of MT in literacy development in Southern Nigeria. After the golden age of literacy in the country, the Nigerian Federal Government, by underfunding education, also hindered the ultimate development of literacy in the country. The Nigerian military government was more or less a surrogate of the feudal oligarchies in Northern Nigeria. The feudal oligarchies did not want the majority of the people in the country to have sound education, which could empower them with literacy and, by implication, liberate them from the shackles of feudalism. [Godonoo \(1991, p. 81\)](#) has observed that Nigerian politicians make “deceptive statements about literacy” and cited both [Ihejieta-Aharanwa \(1989\)](#) and [Brown and Tomori \(1979\)](#) for instances of misleading promises.

In the 1970s the Federal Military Government took over primary and secondary schools in the country. It vested the running of the schools to state governments. However, the state governments, through the underfunding of education, ran the schools down. As [Unoh \(1980\)](#) and [Omojuwa \(1984\)](#) have pointed out, many of the graduates of our primary and secondary schools all over the country can hardly read and write fluently in either English or in their MTs.

However, there were later efforts by some state governments, such as Rivers State in the South-South and Anambra State in the South-East of Nigeria, to redress the issue of government take-over of mission schools. In 2011 Anambra State established the Public Mission Partnership which returned mission schools formerly taken by the Federal Government to the original owners. Under the partnership, Anambra state government remained in charge of payment of salaries of teachers in the returned schools and also provided regular subventions to missions to manage the schools. However, the non-replacement of teachers due to attrition, retirements and deaths over the years have led to insufficient teachers in the schools, leaving the public schools grappling with insufficiency of teaching staff; which no doubt impinges on literacy. The public mission schools are dealing with the issue by permitting Parents Teachers Associations (PTAs) to recruit teachers as the need arises. Such employment has increased the burden of staff salary and caused an increase in tuition. Thus, the schools are becoming both elitist and out of the reach of the poor. A well-intended model is gradually being destroyed.

Generally, education in Nigeria is confronted with significant challenges that include poor funding, poor infrastructure, inadequate classrooms, inadequate teaching aids, inadequate and poor treatment of teachers, and many others. Successive governments have demonstrated a lack of political will to redress these problems and encouraged a growing contention that the government utilizes illiteracy as a means of impoverishing the masses and keeping them under manipulative control ([Oyedepi, 2007, p. 8](#)). The situation in Nigeria is compounded by the “attitude of the technocrats toward issues of literacy and adult education. Literacy has always been relegated to the background” ([Oyedepi, 2007, p. 8](#)). The deliberate neglect of education has made illiterate people living in poverty to accept their unfortunate state as normal. Indeed “it may also be true that the illiterate population have unsatisfactory or unacceptable attitudes toward literacy and education in general because, as they may argue, if their children who are lettered are unemployed what use would their own literacy be” ([Oyedepi, 2007, p. 9](#)).

The systemic disinterest in literacy has also been manifested in the level of support for language-based and literacy-related researches and projects in Nigeria. For instance, in the study “Profile of Education and Language in Nigeria from 1970 to 2019,” [Egbe and Ayeni \(2019\)](#) showed that beginning from the Primary Education Improvement Project (PEIP) in Northern Nigeria in 1970 and the Six-Year Primary Project popularly known as the Ife Primary Education Project also in 1970 in the South West, to the present, these projects have largely been funded by international donor agencies with very little support from local funding by Nigerian government. What this profile shows is that the past efforts to propagate literacy in Nigeria have met with failures because, as important as it is, literacy has always been ignored, poorly funded and not given appropriate position as a vital tool in the process of development and as the fulcrum of formal education ([Adedokun and Kayode, 2019](#)).

Apart from perceiving literacy from the narrow lens of being the ability of merely reading and writing, the NERDC does not seem to appreciate the centrality of reading in literacy. The Council has failed to realize that:

Reading is so interrelated with the total educational process that educational success requires successful reading. Experience has taught us that those who fail in school have failed first in reading. Giordano Bruno pointed out that if the first button of a man's coat is wrongly buttoned, all the rest are certain to be crooked. Reading is the first button in the garment of education.

[Dechant \(1977, p. 1\).](#)

Unfortunately, there is no serious provision for the teaching of reading in Nigerian schools. In an extensive study of how reading is taught in Nigerian secondary schools, [Kolawole](#) observed that 70% of teachers observed did not teach reading. 60% of the teachers felt that the teaching of reading should be handled by the English language teachers. The remaining 40% encourage their students to read if they want to pass examinations and “if they wished to do well in their academic work. Our library observation showed that close to 90% of the schools visited had no functional library; the 10% that indicated they had libraries had no adequate books in school subjects for students” ([Kolawole, 2009, p. 394](#)). As long as there are no qualified teachers who should supervise what is being taught, how it is being taught, and who should ensure that there are adequate materials for teaching and learning, optimal and maximal literacy empowerment cannot be attained in Nigeria.

The lack of political will to implement the Nigerian National Policy on Education (NPE) hinders the attainment of a robust and dynamic literacy position in the Nigerian educational system. For instance, the NPE stipulates that in the first 3 years of primary

school education, the MT of the child or the MT of the child's immediate community should be the medium of instruction. The Ife Primary Education Project that took place between 1970 and 1978 (Fafunwa et al., 1989) proved that when Nigerian children are taught through their MT, they learn all school subjects better than when they are taught through English. Unfortunately, the NERDC and both the Federal and State Ministries of Education do not have the political will to implement the MT medium policy and so straight-for-English teaching is the norm and not the exception.

The literacy rating of Nigeria is poor (UNESCO, 2012) and the efforts of the Nigeria government toward improving this poor literacy rating appear to be feeble in terms of policy making, policy implementation, and budgetary allocation (Onukaogu, 2012). According to UNICEF (2019), a fifth of the global population of out-of-school children are Nigerian. In 2009 regarding formal education, 69.1% Nigerians were literate. In 2015 the rate dropped to 59.6% showing a drop of 9.5%. In non-formal education in 2009 the literacy rate was 57% but in 2015 the rate dropped by 8%–49% (Opeyemi, 2018). Nigeria does not comply with UNICEF's recommendation that at least 26% of a nation's annual budget should be for education. For instance, in 2017, only 7.04% of the Nigerian annual budget was set aside for education. In 2018 it was also 7.4% while in 2019 it was 7.5% increasing by only 0.1%. The trend of 6–8% budgetary allocation has become a regular index of educational funding in Nigeria. Given this deliberate under funding, education in Nigeria requires significant intervention. During the golden age of education in the 1940s–1960s there were libraries in regional capitals and divisional headquarters all over the country. For instance, the Eastern Nigeria Library Board in addition to its regional and divisional libraries had mobile libraries, which operated on weekly basis between Enugu the regional headquarters and each divisional headquarter. It had a good book loan program in which book requests could be freighted from Enugu the regional capital to any part of the region. The British Council had big libraries open to the public at the regional and national capitals (Enugu, Ibadan, Kaduna, and Lagos) respectively. Secondary schools had first rate libraries. Such facilities are no longer available in the majority of schools and colleges in Nigeria.

During the golden era of Nigerian education, teachers were supported to attend local and foreign summer schools where they were retrained for more effectiveness and efficiency. Today, sponsored workshops, seminars, and summer schools for teachers are rare. It is clear that Nigeria's federal and most state governments do not care about their inefficient and ineffective planning of education and its negative impact on literacy. That is why Godonoo contended that:

Furthermore, educational planning and implementation in Nigeria has often been hampered with statistical constraints. Usually, planners and administrators do not have accurate figures with which to work For example, during the implementation of the Universal Primary Education scheme in Nigeria, it was projected that "2.3 million students would register during the first year of the program in 1976. It was however observed that over 8 million students registered." This difference between the projected and the actual figures created a lot of unforeseen problems in the areas of manpower requirements, classroom accommodation, and general facilities.

Godonoo (1991, pp. 84–85).

The Federal Ministry of Education took a significant step toward improving literacy in Nigeria in the project, Education for Change—A Ministerial Strategic Plan (2018–2020) by devoting a chapter to youth and adult literacy. The document admitted that this sector of education had been neglected over time and listed the reasons for the negligence to include poor and inadequate planning, lack of political will, and poor utilization of human and material resources, among others. The Ministerial Strategic Plan is an effort to refocus on both formal and informal education, which has been neglected for decades. The impact of the deliberate neglect of education has also affected the robust and dynamic development of literacy in Nigeria.

Leaping into action: the impact of Nigerian academicians

Academicians contribute to efforts to reposition literacy and overall education in Nigeria. They work from different professional group platforms and employ strategies that include: professional networking/development, engagement, advocacy, and intervention in collaborations with government and non-governmental agencies. Although their areas of focus differ, these associations generally promote aspects of education including literacy. They include the Academic Staff Union of Universities (ASUU), Reading Association of Nigeria (RAN), English Language Teachers Association of Nigeria (ELTAN), Nigerian Mathematical Society, Nigerian English Studies Association (NESA), and the Linguistics Association of Nigeria (LAN). RAN and ELTAN represent examples of groups of Nigerian academicians relentlessly endeavor to improve Nigeria's literacy rating and the quality of education available in schools.

The Reading Association of Nigeria (RAN) was formed in 1982 by a group of Nigerian academicians in order to reposition literacy to what it was during Nigeria's golden era of education. Through national and international conferences, workshops, round tables, seminars and symposia, RAN mitigates the challenges of literacy in Nigeria. The association convinced the Federal Ministry of Education to launch the Read Campaign; a project that promotes reading awareness nationwide, workshops, and roundtables for the professional development of classroom teachers.

In 2001 and 2004, RAN with the support of the World Bank undertook an extensive survey of literacy teaching and learning in all levels of the Nigerian school system. The survey showed that literacy was not taught in different levels of the school system except for adult literacy in the Departments of Adult Education in Nigerian universities. Literacy was only taught tangentially as listening, speaking, reading and writing in English language lessons in primary and secondary schools. Taught as atomistic skills, it was hoped that the learner would integrate them into literacy. It seems to us that many learners never integrate them.

The English Language Teachers Association of Nigeria (ELTAN) was founded in 2004 by some academicians through the efforts of Dr. Patience Ezinwoke and Dr. Felicia Moh to fill the gap in in-service teacher training and literacy development by forming a network of teachers of English at all levels of education in Nigeria. With the initial assistance of British Council, the association operated monthly workshops in which some members and other experts facilitate on chosen topics. The monthly workshops are organized at state chapter levels while an annual national workshop/conference holds between August and September every year. The basic networks include common regular group of-line events and online platforms, which are utilized in sharing resources and good professional practices. The wider networks include collaborative work with other organizations (RAN, British Council, the US Department of State, publishers, government agencies, etc.) and affiliations with associations of similar interest (Africa TESOL, IATEFL, etc.). Between 2005 and 2021, ELTAN has secured various grants from English Language Teaching Contact Scheme (ELTeCS), the US Department of State, British Council, etc. to execute national, regional, and international events that enhance literacy and the teaching and learning of English in Nigeria and other African countries.

ELTAN, in collaboration with British Council Nigeria, has played significant roles in promoting English language professional development and literacy via English in Nigeria. The association has partnered with British Council on literacy-based interventions in Northern Nigeria. RAN has also collaborated with ELTAN on many English language teaching (ELT) and literacy projects. ELTAN has active branches in twenty-nine states of Nigeria through which it drives literacy education. In 2018, ELTAN initiated the Language Resources Project; a collaboration of the Association, British Council, and the National Nomadic Education Commission (NNEC) to alleviate the challenges of teaching and learning literacy in the difficult circumstances of insecurity in North Eastern and North Western states in Nigeria. ELTAN has also enabled teachers and pupils in different parts of Nigeria to benefit from the Association's professional networking, sharing of good practice, workshops, conferences, publications, etc. and facilitated the cascading of RAN's LEAP through its chapter networks. The British Council is further enhancing the literacy empowerment content of its education promotion drive in the North through its Supporting Pedagogical Rigor in Networked Teaching (SPRINT) and its Stimulating Teacher Resourcefulness in Digital Education (STRIDE) in the Federal Capital Territory (FCT), Kaduna and Lagos. Through its collaboration with ELTAN in the North and sustained implementation of SPRINT and STRIDE, the North now even has the potential of not only equaling the South but also surpassing it in its literacy drives.

Gestating and birthing literacy for life-long learning in Northern Nigeria

While Koranic education emphasized rote learning where the pupils were taught recitation and were never given the literacy empowerment to read and write texts, store in writing what they had written and dialog with others regarding what they had written, their counterparts in schools in the rest of the country had such empowerment. This is because schools in the rest of the country had used literacy, the pivot of Western formal education in teaching and learning. The Federal Government of Nigeria and its development partners has taken deliberate measures to ensure that all Nigerian children irrespective of their geographical locations are optimally empowered with literacy for lifelong learning. However, some of Nigeria's development partners like the USAID, the World Bank, British Council, Action Aid, UNICEF, and UNESCO went the extra mile to promote literacy and Western education as instruments for attaining sustainable development in the North East and North West. We shall briefly mention some of the Nigerian development partners and some of the steps taken that have in recent times made the people of the North East and North West invest in Western formal education and are now vigorously implementing literacy empowerment in their schools.

In December 1989, the Federal Government of Nigeria established NNEC to provide formal Western education to children of herders. The idea was to make the nomadic people realize that formal Western education would enhance their productive capacity. In addition, the government wanted the herders to know that formal Western education could complement Koranic education. Specially trained personnel were attached to the herders who trained their children to not only read and write in their mother tongues but also learn conventional school subjects. The response to nomadic education was quite encouraging. Both the children of the herders and their parents came to appreciate formal education as a way of life. Because of the improvement in literacy learning, the mandate of NNEC was extended to also cover all migrant farmers and fishermen in the riverine areas of the country.

The Federal Government also set up the National Commission for Mass Literacy and Adult Non-Formal Education (NCMLANFE) in 1990. The basic aim of NCMLANFE was to empower illiterate Nigerian adults with literacy. Since the Christian missions in Nigeria had adult literacy programs for the illiterate adults in their respective congregations the focus of the NCMLANFE should have been more concentrated in the Northern part of the country where Christian missions had very few mass literacy programs for their illiterate adults. The activities of NCMLANFE failed to meet its objectives. For instance, it did not employ competent professionals who could handle the literacy development of adults. Besides, enough materials specific to the mother tongue literacy needs of the illiterate adults were not available to sustain the program. It appeared also that those assigned to teach the illiterate adults were not properly remunerated for their efforts. Thus, while the policy formulators of the program had mouth-watering incentives, those who actually did the teaching were demoralized. Thus, whether, in the North or South, the generality of illiterate adults were not interested in the mass literacy and adult non-formal education. However, advancement in literacy teaching and learning was made in formal education in Nigeria when the Federal Government launched the Universal Basic Education (UBE) program in 2004. The Universal Basic Education Commission (UBEC) was set up to oversee all aspects of the UBE at both the Federal and state levels. At the state level, the Universal Basic Education Board (UBEB) was set up to implement the policies of UBEC. Three percent (3%) of the federal budget was set aside for the implementation of UBE. The 6 years of primary and 3 years

of junior secondary school which were funded by the Federal Government have impacted very positively on literacy teaching and learning in the country. In order to further boost literacy teaching and learning in the North, the Federal Government has taken steps to integrate Koranic Schools in the North with conventional Western formal education. When this bold step of the Federal Government is fully implemented, literacy empowerment would be achieved in Northern Nigeria.

The World Bank has taken dynamic steps to promote literacy empowerment among teachers and learners in Nigeria, especially Northern Nigeria. Based on the success of its pilot program in some selected Northern states, the Bank has in its "Basic Education Service Delivery for All" (BESDA), decided to improve education in the North East and North West of Nigeria. Since the Bank has observed, "Enrollment rates in basic education are also marked by gender disparities and wide variation across zones of Nigeria, with the North East and North West demonstrating lower outcomes" (World Bank, 2017, p. 3), all the states in the North East and North West are covered in its BESDA initiative. The Reading Association of Nigeria (RAN) is partnering with the Bank in actualizing the literacy component of BESDA. RAN had collaborated with the Bank in implementing similar projects in Anambra, Ekiti and Osun states. We believe that if current efforts are sustained, the literacy rating of the North would be more positive in the future.

Since 2000, RAN has collaborated with the USAID in implementing its education programmes in the country. For instance, RAN has collaborated extensively with USAID in its Northern Education Initiative Plus (NEI Plus), a pilot project in Bauchi and Sokoto states designed to provide quality education especially for girls and out of school children in the two states. Apart from enabling the project partners to strengthen the abilities of local government authorities to better train and manage teachers, plan budgets, mobilize community support for learning, ensure timely distribution of learning materials, RAN in collaboration with NEI Plus established 400 Community Reading Centers or Hubs and 100 Reading Forums in schools in 10 Local Government Areas of each of Sokoto and Bauchi states. RAN also produced Community Reading Charter which captured the role of stakeholders in improving education in both states through literacy empowerment. All the materials produced for literacy teaching and learning are in both the mother tongue and in English. It is important to note that the establishment of a National Reading Research Center in Ado Bayero University, Kano state, is a result of USAID's investment and promotion of literacy in Northern Nigeria.

The literacy enhancement and achievement impact

RAN, in collaboration with the Anambra State Ministry of Education, has developed the Literacy Enhancement and Achievement Paradigm (LEAP). RAN is using LEAP as a paradigm shift to enhance literacy and overall education standard in Nigeria. LEAP is anchored on five strong pillars:

First, the thorough training of literacy teachers is mandatory because literacy is a discipline demanding multi layered knowledge, attitudes, and skills. Second, in LEAP an appropriate atmosphere must be deliberately created so that learners are surrounded with the atmosphere that entices and excites them to acquire and practice literacy. Group and individual practices for literacy are provided since interaction among members of literacy community is central to its acquisition. In order to ensure that Nigerian learners have the atmosphere that would make them learn and practice literacy, we had to empower classroom teachers in primary and secondary schools on literacy development. The empowerment was achieved by ensuring that the teachers were retrained on the knowledge, attitudes and skills required in literacy education. Since most of our primary and secondary school teachers were not taught literacy and how to teach it during their secondary and tertiary education, they could not effectively and efficiently teach it. LEAP is designed to fill the gap for them by developing their professional skills on literacy education.

We therefore organized a master-trainer workshop for two hundred and twenty Master Trainers drawn from the twenty-one educational zones in Anambra state. We brought in Dr. Alice Headlam to train the Master Trainers on what literacy education. Dr. Headlam is a freelance literacy consultant who was a Chair of the International Committee of the Whole Language Umbrella. She has tremendous experience teaching literacy in the Caribbean. She was assisted by RAN consultants - Professors C. Muodumogu, S. Ekpe, G. Egbe, K. Omenugha, C. Onukaogu, G. Oyinloye, G. Ofudu, and Dr. J. Ahaotu - who as past presidents of RAN and professors of Literacy Education and Communication Studies helped to guide Dr. Headlam to tailor her vast experiences and expertise to meet the needs of the Master Trainers (Fig. 4).

The Master Trainers' workshop lasted eighteen days; 8 h a day except for Sundays. The workshop had extensive hands-on activities. It made provisions for micro teaching by the Master Trainers under the supervision of Dr. Headlam and the RAN consultants. The workshop model of instruction was used, making use of mini lessons and activity periods, sharing and vetting what was practiced. It was therefore easy for the Master Trainers to practice what was taught and see the strengths and challenges in literacy teaching and learning. The workshop modeled how the Master Trainers can reinforce the strengths and address the challenges of their trainees and pupils.

At the end of the master trainer's workshop, they were sent to their respective education zones to replicate and reinforce the knowledge, attitudes and skills they had acquired at the workshop. We set up school clusters at the education zones where the Master Trainers replicated what they had learned. Each cluster consisted of six schools that were within walking distances from each other. The school that was at the center of the cluster was made a meeting point for the teachers in the cluster. The cluster training session lasted for 9 months during which two Master Trainers were sent to each cluster to train all the teachers there.

Each teacher in the state was given a copy of *Tool kit*, a resource material on literacy teaching and learning. It consists of commissioned articles on literacy teaching and learning written by veteran literacy education consultants drawn from Nigeria, the UK and the USA. Each teacher in the state was also given a copy of *Teaching Reading in Nigeria: A guidebook to theory and practice* edited by

Fig. 4 Dr. Headlam with some participants at the maiden LEAP workshop. Courtesy: RAN Executive album.

Professors C. Onukaogu, A. Arua, and T. Jegede. The book had commissioned chapters on various aspects of literacy written by veteran literacy specialists within and outside Nigeria. The book provides current and proven trends in literacy teaching and learning, which could empower the classroom teacher to make a positive difference in literacy teaching and learning in Nigerian.

Each teacher and each pupil in the state was given a literacy journal. The journal promoted variation of classroom interaction patterns—teacher/teacher, teacher/learner, and learner/learner. The journal thus provided a wonderful opportunity for learners and teachers to read, listen to what is read, write about what they see, hear, and above all interact as a community of literacy learners and teachers.

We had resource centers in each of the twenty-one education zones in Anambra state, each equipped with state-of-the-art resource materials on literacy teaching and learning. Each teacher in any cluster has access to the resource materials and could borrow books from there. We also had thirty-six monitors who supervised classroom teachers in order to ascertain the strength of the teachers and the challenges they faced in implementing what they had learned during their training at the cluster level. The monitors were trained to enable the teachers to overcome their challenges as well as reinforce their strengths. The monitors reported to the RAN consultants at the project headquarters.

From the report of the monitors we found that teachers were too pre-occupied with testing and so we brought in Professor Rob Tierney from the University of British Columbia, Canada to train the Master Trainers on Portfolio Assessment in a five-day intensive workshop (Fig. 5). At the end of the workshop, the Master Trainers proceeded to the clusters to replicate the training. Similarly, the report of the monitors, showed that teachers were deficient in the handling of challenged learners. We therefore had to bring in Dr. O. Abiodun-Ekus of the University of Reading, UK, to address the problem of teaching literacy to challenged learners in a three-day intensive workshop for the Master Trainers.

Fig. 5 Prof. Rob Tierney and Prof. Emeka Onukaogu (fourth & fifth from the right) with some RAN Project Consultants. Courtesy: LEAP project album.

We were able to make both teachers and learners participate actively in literacy teaching and learning through the following channels:

- (1) Competent classroom teachers who replicated what had been modeled in the Master Trainer's workshop;
- (2) Extensive resource materials which teachers had access to freely and fully; and
- (3) Effective patterns of interaction: teacher/learner, learner/learner and learner/teacher classroom interactions that were based on best practices and proven interactions strategies.

The third pillar of LEAP is achievement in which learners are encouraged to have as diverse opportunities as possible in using literacy. Before LEAP was introduced as a paradigm shift for the teaching of literacy and reading in Anambra state, the teaching of reading and literacy there was a nightmare to pupils. Reading was poorly taught and whole literacy was not taught to the pupils. After reading a given text, pupils were required to answer questions on the texts they read. It did not matter whether or not the texts were within the readability levels of the pupils and students or whether the contents of the text were culturally relevant to them. The teachers showed the learners their poor performance at the task/test. The reasons why the pupils performed so poorly in the tests were hardly explained to them. In addition, they were never taught how to read and comprehend texts generally. It was assumed by the teachers that once pupils and students can decode the words in a text, they were literate, and could therefore read and comprehend any text placed before them. The teachers were not familiar with the components of reading, the levels of reading, the levels of reading comprehension and the readability levels of the learners. The teachers were ill-equipped on how to teach reading and measure the performance of students and pupils when they read. The pupils were demoralized by their achievement and did not see any link between their reading/literacy lessons and their mathematics, science, history, and everyday life; they only saw reading and literacy in the context of English language.

When LEAP was introduced as a paradigm shift in the reading and literacy lessons, the narrative changed. Story-telling and retelling were introduced into reading and literacy lessons. In LEAP the teacher had the responsibility of searching for interesting and exciting stories. Using the principle of drama, the story would be told the pupils and they would be asked to retell the story orally and were never discouraged, derided, or criticized during an oral retelling session. When they had shown mastery of oral retelling, they were in practice sessions shown how to retell the stories in writing. Furthermore, the Directed Reading and Think Approach (DRTA) was used in enthusing the pupils to enjoy reading, listening, and writing. Exciting stories were read aloud to the pupils and students. They were asked such questions as—what do you think would happen next? Why do you say so?—that would make them participate in the Read Aloud. Such questions motivated them to predict what would happen next when the reading stopped at certain intervals.

The various methods adopted in LEAP allowed the students and pupils to participate actively in the reading and literacy lessons. Texts were also taken from the mathematics, science and technology textbooks. Using very exciting methods, such texts were jointly read by the pupils and their tasks jointly performed by them. The fun which the students derived when such texts were read aloud together in the class and also analyzed together made the pupils not only enjoy the lessons but also looked forward to having them. We took time to teach and model text processing strategies so that the pupils could read easily at the instructional and independent levels. In the area of comprehension, we modeled interpretive, critical, and creative comprehension strategies. We used diverse kinds of texts to model what we wanted the students to master. The use of journals for interactions among the learners and with their teachers was very interesting to them; fluency was emphasized rather than too much emphasis on grammatical accuracy. Later, the pupils were able to write their stories and autobiographies which we desktop-published for them (Fig. 6).

Fig. 6 Samples of learners writing that were desk-top published. Courtesy: LEAP Project Album.

One interesting hallmark of LEAP was that it de-emphasized testing. We adopted the Portfolio Assessment model in collecting information regarding the performance of each pupil. We did not compare the performance of any pupil with that of others. We monitored the performance of each pupil at the commencement of the year, at the mid-year and at the end of the year, based on the data we collected from the portfolio of each pupil or student. Each student also had a strong input regarding how s/he was assessed. At the end of each year, it was celebration galore as each learner has something to celebrate.

The fourth pillar of LEAP is a blend of teacher centeredness with learner centeredness, giving rise to learning centeredness. Thus, in LEAP both process and product synchronize into learning-centeredness. Three significant pendulum shifts are identifiable in general literacy and language teaching methodology. First, in the 1950s and 1960s the literacy teaching and learning pendulum swung to the extreme left where the teacher was the most significant element in literacy teaching and learning. This was a teacher-centered swing which emphasized the teacher as the center in literacy teaching and learning. The learner was treated as a tabula rasa; an empty slate that had nothing to offer in literacy learning and teaching. Given the overbearing and towering image of the teacher, what mattered to the learner was “what my teacher says,” while what mattered to the home of the learner was “what did your teacher say?” However, from the 1970s, there was another pendulum swing from the far left to the far right. This time the swing emphasized the learner. Literacy teaching and learning strove to be learner-centered. The emphasis was no longer on who does the teaching but on who does the learning. However, in LEAP there is now another pendulum swing; this time to the middle. This pendulum swing draws attention to the process of learning. Thus, while the teacher does the teaching and the learner does the learning, LEAP takes the position that if we can understand how the learner learns and uses literacy, we are more likely to address the needs of the learner. Learning-centredness is primarily an amalgam of teacher-centredness and learner-centredness. Thus, while learning-centredness draws attention to the process of learning, the other two emphasize the product of learning from the position of the teacher or from the position of the learner. For optimal performance in literacy teaching and learning, LEAP contends that the three approaches must symbiotically interplay and interrelate.

The fifth pillar of LEAP is celebration. Celebration is infused into LEAP in order to make the learner and the teacher realize that the society treasures their efforts at literacy learning and teaching. That is why at every point of learning and teaching both the learner and teacher are celebrated. That is also why the climax of celebration in LEAP is a Literacy Festival where the works of the literacy learners, teachers and literacy stakeholders at the home, the community, and school levels are celebrated (Fig. 7).

The efficacy of LEAP is reflected in the pilot study carried out in three local government areas (LGAs) of Anambra State—Orumba South, Awka South and Anambra East. The 7500 students who were taught during the pilot implementation of LEAP were tested in English, Mathematic, Basic Science and Technology. They had an average score of 30%, 25%, 25% and 20% respectively in the pre-test. Half way in the program, a mid-course test was administered to the students. They scored 60%, 60%, 50%, and 49% respectively. The post-test was administered at the project completion. Trainee performances in the four subjects were 80%, 85%, 70% and 80% respectively.

The impact of LEAP is felt within and outside the country. For instance, in 2018, Anambra State students won the gold medal in the Silicon Valley, the United States of America global competition of students with their production of an appliance for identifying fake drugs (Fig. 8). In 2019 Anambra State students won the bronze medal in international Festival of Science and Technology (IFEST). Since 2016, Anambra state students have appeared among the three best states in West African School Certificate

Fig. 7 Celebrating excellence with pupils who won prizes at the Literacy Festival From the left: Prof. Omenugha (Honorable Commissioner of Basic Education, Anambra state and contributing author to this chapter) Executive Governor of Anambra state, Mr. Willie Obiano, his wife, and Prof. C. E. Onukaogu (Chairman, Board of Trustees, RAN and lead author of this chapter) with three pupils who received prizes at a Literacy Festival. Courtesy: Prof. C. E. Onukaogu's Library.

Examinations in Nigeria. Moreover, the state for three consecutive years won gold in the national debate championship organized by the Presidential Schools Debate of Nigeria.

One of the outcomes of LEAP in Anambra State was the improvement in the reading levels of the students. Before the commencement of LEAP, data showed that 76% of the students read at the frustration level. At this level, the students are able to decode some words in the text but cannot comprehend the text even if they receive assistance from a teacher. Only 14% of students read at the instructional level. At this level the students have some challenges in comprehending the text. However, with assistance from their teacher they can overcome the challenges. The data showed that 10% of the students read at the independent level. At this level the students can comprehend the text without any help from their teachers. LEAP engendered a reversal of the reading levels of the students and only 33% read at the frustration level, 47% at the instructional level and as many as 43% at the independent level after the project.

Given the successes of LEAP, the Anambra State Government with funding from the World Bank, collaborated with RAN to implement LEAP in all the primary schools in Anambra State. Also, the Ekiti State Government in collaboration with RAN is implementing LEAP in all the primary schools in Ekiti State in South-West Nigeria.

Conclusion

This chapter has traced the trajectories of literacy in Nigeria and how entwined it is with politics and other socio-cultural forces. A number of issues stand out in the discourse. First, the concept of literacy in Nigeria has undergone numerous changes—from oracy as an indigenous form of literacy to the traditional 3Rs (Reading, Writing, & Arithmetic) of Western literacy. The 3Rs, an autonomous model of literacy has also been interrogated, with the new literacies emerging. The new literacies are of the ideological model that derives from a wider perspective of intellectual and social perspective of learning, knowledge, attitudes, and skills. Second, in all these forms of literacies, politics has continued to play a role in suppressing or enhancing literacy. The politics of suppression is evident in literacy practices in Northern Nigeria where only recitation of Koran in Arabic was taught to the pupils—giving the people no opportunity to read, write or calculate (even in Arabic). This has kept the people under the dominion of the fiefdom. The long-term effect is that in the present times, the Northern Nigerians have remained predominantly illiterate; having not been exposed to literacy for life. This has also resulted in Northern Nigerians hating Western education and further remaining predominantly illiterate. The Christian missionaries in teaching the 3Rs did so, not in the MT, but in English, which became a language of domination of the local people. The colonial government used literacy to socially control and repress the people, making them submissive.

One would think that with independence and the taking over of schools from the missionaries by Nigerian government, a different narrative would emerge. Not only did the story not change, it appeared worse as many of the schools now put in the hands of government suffered neglect, dilapidation, and an almost total collapse of education and literacy. The government failed to give education the priority it deserves through poor policies, inadequate funding, mismanagement, and inability to address the mounting challenges and problems in education. Literacy was not prioritized as a subject to be taught in schools. The result is that teachers are ill prepared to teach the reading component of literacy and many students and pupils continue to read at frustration level. There have been attempts to bring new models of education such as Public-Mission model as seen in Anambra state of Nigeria. In this model, while the mission is in charge of administration of schools, the government pays the teachers. It is hoped that the model would enable the missions to bring back the golden era of education in Nigeria where teachers attended summer schools and libraries were functioning. The challenge has been that the government fails in the crucial responsibilities of effectively funding and supervising education, including teacher welfare and continuous professional development.

The Nigerian educational sector requires a political will and consistent, massive budgetary allocation by the government to improve it. Ebi and Ubi's (2017) analysis submitted that an implementation of UNESCO's recommended 26% expenditure on education in Nigeria would have had 19-times the impact on access to primary school enrollment, more than 2-times the impact on secondary school enrollment and 9-times the impact on access to tertiary education, and create an average of 10-times greater access to overall education in the country. These implementations could redress the decades of neglect and reposition formal education to desirable standards in the country. The efforts of government at various levels to provide free basic education and recent policy adjustments such as the Ministerial Strategic Plans (2018–2022) hold potentials of improving education in Nigeria if they are effectively implemented. ASUU has also relentlessly engaged the government and championed the cause of improvement in Nigerian universities. Also, RAN is collaborating with the World Bank, State Ministries of Education, State Universal Basic Education Boards and International Agencies like the USAID and DFID to highlight the central and pivotal role of literacy in formal education in Nigeria. Given the increasing interventions and many education initiatives in Nigeria, such as the World Bank's Better Education Service Delivery for All (BESDA), the USAID/DFID's NEI Plus Initiative, and others, there is hope of improvement in education and its literacy component in the country. Such improvement must take cognizance of the changing times which herald increasingly complex literary demands.

Co-authors as Indigenous scholar-practitioners

As Indigenous scholar-practitioners from four distinct Indigenous communities who engage in the work of our traditional homelands—Hawai'i, Kanien'keha:ka, Lytton First Nation, Isthmus Zapotec—and in language revitalization efforts, we have many responsibilities that shape/determine how we participate in the various domains of which we are a part (e.g. the academy, schools, communities, cultural practices). It is important for us to articulate that although we have been educated and continue to work in Western institutions, our knowledge base is grounded in our respective Indigenous ways of knowing and being. We collectively continue to live and practice our lifeways even as we each currently reside away from our traditional homelands.

To privilege and promote our Indigenous languages, we have chosen to use our languages throughout the chapter (sometimes without a translation requiring the reader to make meaning through context, inquiry, research, and embodied understanding), employing and emphasizing Indigenous languages amidst the dominant language of English. We offer relevant websites to extend readers' understanding of the word or phrase. However, please note that these resources should be used responsibly with the utmost respect, as they are for the benefit of Indigenous Peoples of specific communities, first and foremost. Only when the language and knowledge are used *in relationship with* Indigenous Knowledge Keepers and Holders can one *begin* to understand the complexities of a concept embedded in Indigenous epistemologies, axiologies, and ontologies. We also recognize that by using a colonial language we are able to reach a much broader audience. Part of Indigenous Peoples' linguistic and cultural re-generation and resurgence is understanding what our kuleana (right, privilege, concern, responsibility) is to our homelands, and how we are accountable to our places, lands, and peoples.

Aloha. 'O Candace Kaleimamoowahinekapu Galla ko'u inoa. He Kanaka Hawai'i a Pilipino au. No Pāhala mai au ma ka moku-puni nui o Keawe. Ke a'o mai nei au i ka 'ōlelo Hawai'i i mea e ho'onaauao ai ia'u iho ma ke 'ano he Hawai'i a me ka ho'omau 'ana i ka 'ike Hawai'i no na hanauna e hiki mai 'ana. He poloheka hope ma ke kula nui o Kolumepia Pelekānia ma Wanekouwa i Kanakā i ka Hale Ho'ona'auao Ha'awina Kālailai 'Ōiwi (Kumu Pāheona) a me ka Māhele 'Ōlelo a Ho'ona'auao Heluhelu (Kumu Ho'ona'auao). Hello, my name is Candace Kaleimamoowahinekapu Galla. I am Hawaiian and Filipino from the island of Hawai'i. I am learning my language to strengthen my identity and to perpetuate the Hawaiian culture for the next generations. I am a professor

at the University of British Columbia in Vancouver, Canada in the Institute for Critical Indigenous Studies (Faculty of Arts) and the Department of Language and Literacy Education (Faculty of Education).

She:kon. My name is Amanda Holmes. I am Kanien'keha:ka on my Mother's side, and Highland Scottish on my Dad's side. I grew up near Onawi:io. I grew up without my language. I have been in the process of returning to and re-learning my language since my mid-twenties. I have had my Clan returned to me and it is hung around my neck. I am Turtle Clan. My community is Kanatsiohareke Mohawk Community in the Mohawk Valley.

Paduxi Na Laya Joshua Schwab Cartas. na naca binniza, Nacá baduhuni Gilberto Cartas Posada ne binilidxe Cartas Arias ne Ranchu Gubiña, ne Na Lilia Guzman Cartas laabee Ixtepec (San Geronimo) ne xtinne' binnilidxe Arias Cartas binni Ranchu Gubiña ne binilidxe de Vancouver and Montreal Canada na riniisi. Hello, my name is Joshua Schwab Cartas. I am of binniza (Zapotec)—the grandson of Gilberto Cartas Posada and family member of the Cartas Arias Family from Ranchu Gubiña, as well as the grandson of Lilia Guzman Cartas from Ixtepec (San Geronimo). I also have family in Vancouver and Montreal Canada where I grew up.

Nlaka'Pamux N'Chowa, Esquesht Pubska, Daquiyantsa Aguawn Kumcheen. I am Billy Rowluck and am a member of the Nlaka'Pamux Nation. My home community is Lytton First Nation, located at the conflux of the Thompson and Frazer Rivers in British Columbia. I entered public education in 1996 as a teacher's assistant and went on to earn a bachelor and masters of Education from the University of Saskatchewan. My experience has ranged from classroom teacher to principal in two northern schools in Saskatchewan. I am currently a doctoral student at the University of British Columbia in the Department of Language and Literacy Education and am interested in the representation of Indigenous ways of knowing within public-school curriculum.

Lighting the way home

Of the 7000 languages spoken in the world, 2680 languages are at risk (UN, 2018) of no longer being spoken or passed down to future generations. By contrast, "About 97% of the world's people speak about 4% of the world's languages; and conversely, about 96% of the world's languages are spoken by about 3% of the world's people" (Bernard, 1996, p. 142). Scholars in linguistic human rights, Skutnabb-Kangas and Phillipson (2010) warn that, "Almost all languages about to disappear would be indigenous, and most of today's indigenous languages would disappear, with the exception of very few ..." (p. 77).

This chapter discusses Indigenous language restoration, renewal, recovery, and resurgence, its spaces, contexts, practices, and possibilities, decolonizing spaces that hold the aspirations of their People for returning to their language, as their language lights the way home to Indigenous understandings of relationality, the interbraiding of cultural coherence, collective narrative memory (McLeod, 2007), and intergenerational relationship. Indigenous Peoples hold ancient connections to their languages and their lands; it is in relationship with their lands, waters, and natural world that their language and their own existence as a People have been formed and, in expressions of deep reciprocity, have given each other life. Widespread among Indigenous Peoples is the strong feeling and love they hold for their language, languages often understood as a sacred gift from their Creator, connecting them to their Ancestors, to their lands and lifeways, to their teachings and ethical principles, to their knowledge systems and ways of knowing-being since time immemorial; these are understandings that define *who they are* as a People.

From within this context of longevity on their lands – the intricate, intimate textures that form vast webs of relationship particular to home, land, language – the experience of colonization has wreaked havoc on Indigenous Peoples, languages, and lands, on the cycles and patterns of relationship that have maintained and sustained Indigenous "survivorship" (Vizenor, 1999) for generations. Indigenous communities continue to work with determination to re-awaken, restore, and renew their languages out of long histories of targeted, strategic language repression that has been a core feature of the settler-colonial project of Indigenous elimination and replacement (Wolfe, 2016). As Wolfe (2016) points out, settler colonialism destroys in order to replace, aiming for "more than summary liquidation, it strives for the dissolution of Native societies" (p. 33). As state policies pursued the dissolution of Native societies through coercion, control, and domination, the eradication and replacement of Native languages proved to be an effective tool in the settler colonial toolkit. Education became an increasingly important arena for settler colonial states to deal handily with "the Indian problem," as physical genocide became tempered by cultural genocide, with the "friends of the Indian" arguing for cultural genocide beginning in the latter half of the nineteenth century in the United States, with Canada soon following its lead. Recalling the blunt words of Philadelphia lawyer Henry Pancoast, "We must either butcher them or civilize them, and what we do we must do quickly" (Adams, 1995, p. 2).

In 1879, the Carlisle Indian Industrial School, which was to become the prototype of Indian boarding schools (and state-sponsored violence in the form of not only brutal physical, sexual, emotional abuse, but also of ethnocide and linguicide against Native children, their families, and communities), was founded under the direction of Colonel Richard Henry Pratt, a veteran of both the Washita massacre of the Cheyenne and the Red River campaign against the Comanche, Kiowa, Southern Cheyenne, and Arapaho, and in charge of the Indian prisoners at Fort Marion in Florida. Pratt participated in multiple contexts in the eradication and extermination of Indigenous people; he has become known for his now infamous operating motto: "Kill the Indian in order to save the Man" (Smith, 2009, p. 5).

In her work on the politics of language, language ownership, and the teaching of English to Native students during the late nineteenth century, Ruth Spack expands on settlers' racialized hierarchies and their technologies of linguistic and cultural replacement, where "Anglo Americans believed in the superiority of their own language and culture, and almost from the beginning they began to develop educational or civilization programs to impose the English way of life on the Native population" (Spack, 2002, p. 3). Soon, boarding or residential schools would become widespread across the U.S. (Lomawaima and McCarty, 2006) and Canada (Truth and Reconciliation Commission of Canada, 2015), as well as in Mexico (Dawson, 2012), India (Gupta and Padel, 2020), Australia (Commonwealth of

Australia, 1997), New Zealand (Walker, 2016), and other regions. While Indigenous children and communities have always found ways to resist enforced schooling (Lomawaima and McCarty, 2006), it is critical to remember that boarding schools were an act of aggression by settler states as “governments intentionally removed indigenous children to institutions as acts of colonial control, not assimilation” (Jacobs, 2006, p. 202), “as an official strategy of ... subjugation” (p. 204).

In international arenas, Indigenous Peoples have fought to have their fundamental rights as Peoples recognized by international bodies, including their rights to their lands and waters, languages, religious freedom, education, and traditional forms of governance. Finally, in 2007 after many long years of intense pressure, Indigenous Peoples from around the world succeeded in gaining the passage of the United Nations Declaration on the Rights of Indigenous Peoples by the UN General Assembly. Although it is beyond the scope of this chapter to provide an exhaustive summary of the national and international language policies and frameworks that impact Indigenous languages, we include several federal US and Canadian policies that attempt to address these countries’ long-standing practices of targeting Indigenous languages for extermination: in Canada, the Indigenous Languages Act (2019); in the United States, the Native American Languages Act (1990), the Esther Martinez Native Languages Programs Act (2006); and the long overdue repeal in 1986 of the Hawaiian Revised Statutes of 1896, a policy that prohibited Hawaiian language medium instruction and contributed to the widespread loss of the Hawaiian language, to name but a few.

The aim of this chapter is to provide a broad overview of Indigenous language renewal and regeneration from diverse perspectives, with resources that the reader might find useful. It should be noted that in any discussion of Indigenous languages, knowledge systems, and cultural practices that have been subjugated by colonization, deeply embedded differentials of power are also present. We are deliberately choosing the language of “community-centered” to describe and discuss Indigenous language renewal efforts that are emergent from within Indigenous communities – they are community-driven and community-led, where the needs of the community are centered (Evans, 2004; McDonald, 2003). Given long, extractive histories, where the tendrils of the academy have reached into Indigenous communities, this is a profoundly critical conversation (Battiste, 2013; Smith, 1999, 2012).

This chapter not only intends to disrupt the academy’s assumption about the necessity and centrality of Western academic research to Native communities’ efforts at revitalizing their languages, it also challenges the academy’s authority to define, delimit, and control the practice, theorizing, envisioning, and aspirations of Indigenous communities for the futurity of their languages. While the impact of colonization has indeed caused enormous cultural and linguistic disruption and upheaval for Indigenous Peoples, communities continue to fight for the continuance of their languages and cultural ways of knowing and being, defined on their own terms, within their own contexts of survival, persistence (Nicholas, 2014), resilience, resistance, self-determination, collective transformation, and resurgence (Galla et al., 2014). This chapter foregrounds self-determining, decolonizing, and transformative research methodologies, epistemologies, and practices of Indigenous language restoration, renewal, and regeneration from community-centered perspectives and orientations. We hope it chips away at the imbalance of power between Indigenous communities and Western academia in the field of language restoration and renewal. We explicitly and self-consciously toss the false Western construction of objectivity to the wind by supporting, promoting, privileging, highlighting, and amplifying Indigenous community language and cultural reclamation work, aligning ourselves with Indigenous community-based, community-centered desires, hopes, struggles, priorities, aspirations, and dreams.

Indigenous Peoples know well that the language we use holds power and contributes to the creation of the world in which we live. Thus, it is even more relevant to be explicit about the language choices we will be using in this chapter, and some of the context and meanings we intend by the particular choice of language we use. A focus on “extinction” characterizes mainstream discourse with regard to Indigenous languages. We align ourselves with Indigenous language advocates, scholars of the community and of the academy, who are contesting and resisting Western discursive framings of Indigenous languages in terms of *morbidity*, *extinction*, and *death*, including the framing of “revitalization” itself. We are thus following the lead of community as they re-frame Indigenous language “revitalization” as language awakening (Hobson, 2010), restoration, recovery, renewal, regeneration, and resurgence. Indigenous communities continue to resist and re-shape the discourse around their language in ways that are more relevant, meaningful, and coherent from within their own epistemologies and knowledge systems.

A few notes on language and discourse must be addressed as we set out on this collaborative thinking to bring some of the historical contexts, diversity, activity, and possibilities of Indigenous language renewal and regeneration to this work. We recognize that all too often, colonizing discourse frames Indigenous languages, shaping the perceptions and attitudes, the “orientations,” (Ruiz, 1984) around “language endangerment” (Dwyer et al., n.d.) that define and delimit Indigenous languages and their revitalization. We wish to cultivate some common ground with which to understand the contexts of Indigenous “language revitalization” or language awakening. We begin with the working definition of Indigenous Peoples used by the United Nations Permanent Forum on Indigenous Issues (UNPFII) as: “Practicing unique traditions, they retain social, cultural, economic and political characteristics that are distinct from those of the dominant societies in which they live. Spread across the world from the Arctic to the South Pacific, they are the descendants – according to a common definition – of those who inhabited a country or a geographical region at the time when people of different cultures or ethnic origins arrived. The new arrivals later became dominant through conquest, occupation, settlement or other means” (UNPFII Factsheet, n.d.).

Further, while acknowledging that efforts at Indigenous language renewal and regeneration emerge from within the particularities of Indigenous places and contexts, we join with Duarte and Belarde-Lewis (2015) who remind us that, “As Kanaka Maoli philosopher Manulani Aluli Meyer asserts, ‘specificity leads to universality.’ Understanding distinctiveness leads us to appreciate how ‘we are all the same, differently’” (p. 678). Indigenous communities continue to work with determination to re-awaken, restore, and renew their languages – and, as we get closer to our languages, there is a distinct sense that our living languages are also at work, waking us up to who we have always been, and who we are meant to be.

Elder praxis, intergenerational knowledge relations, and Indigenous language restoration, renewal, and resurgence

Reciprocity is a matter of keeping the gift in motion through self-perpetuating cycles of giving and receiving ... With their tobacco and their thanks, our people say to the Sweetgrass, 'I need you.' By its renewal after picking, the grass says to the people, 'I need you too.' Mishkos kenomagwen. Isn't this the lesson of grass? Through reciprocity the gift is replenished. All of our flourishing is mutual.

Kimmerer (2013, pp. 165–166).

Indigenous languages hold within them the endlessly renewing cycles of reciprocity and regeneration, carrying ancient teachings, intricately braided knowledge systems, philosophies, principles, and ethical, oral-relational ways of knowing-being that orient and instruct us about our relationships with each other and the natural world, from within the vast “multiverse” (Cajete, 1994, p. 75) of Indigenous contexts of diversity. From within Indigenous knowledge systems and ways of knowing-being, Indigenous Peoples know our languages to be a sacred gift, emergent from within ancestral pasts that are as old as the beginning of Time, giving voice to deep relationships they continue to maintain. It is in our languages that the beautiful and intimate ways we know our lands and waters and the beyond-human worlds, the ways they sound and speak to us, can be heard. Our languages and the knowledges they carry continue to shape our understandings of who we are and who we have been – and guide us to remember who we are meant to be.

Intergenerational knowledge relations

Situated within the particularities of Indigenous universes, these reciprocities of relationship between ourselves, our languages, our Ancestors, the coming generations, and the natural world become illuminated and ignited; and it is through these cycles of renewal and reciprocity that our languages call us into restoring and re-storying our ancient commitment to each other and to each strand of the vast web of relationship to which the People and their languages are connected. Indeed, “All of our flourishing is mutual” (Kimmerer, 2013, pp. 165–166). Indigenous languages tether their People to an intergenerational-relational matrix, to Ancestors and to future generations, and to the regeneration of ancestral memory into today through these relations of longevity and the continuities of intergenerational knowledge relations. Indigenous languages hold and carry the worldviews, teachings, principles, knowledge systems, collective narrative memories (McLeod, 2007), and ethical-relational ways of knowing/being of their People, from deep within their contexts. By restoring, renewing, and regenerating Indigenous languages, the matrix of Indigenous *relationality* is restored, renewed, regenerated. This vast relational web, this multiverse (Cajete, 1994), is the heart center of their People, with each filament connecting to the others through their language, their particular ways of understanding the meanings of who they are and how they are to be in the world. These are the relational worlds that Indigenous languages carry, and it is within these spaces and places of knowing and being as a People that we look to renew and re-generate our languages.

Elder praxis

Indigenous Elders have always held the center of Indigenous life, language, and knowledge, embodying the collective consciousness of their People – and they become ever more important as time passes. It is necessary to clarify the meaning of the term “Elder” when used within Indigenous contexts, as the idea creates some confusion for Western-oriented people, so a brief explanation is needed here. Indigenous Peoples hold a common understanding about the meaning and critical importance of Elders within Indigenous societies, as those who, because of their living and experience, have gained wisdom, widely recognized as spiritual wisdom, which is critical to the life of their People. They hold a revered position in Indigenous societies and are traditionally viewed with great respect. Elders carry the spark that nourish and sustain the social, spiritual, ceremonial, ethical, emotional, physical, intellectual, generational well-being of their People. They are located at a critical nexus of relationship between the generations, a space of exchange and reciprocity between Ancestors and the coming generations. Lakota Elder Rosalie Little Thunder always asserted, “Elders are the mirror of our Ancestors” (Little Thunder, personal communications to A. Holmes). The praxis of Elders (Holmes, 2018) holds the power to invigorate ancient knowledge systems within unfolding contexts of past, present, and future generations. From within their wisdom practices and position of deep respect, Elders hold the possibility for transforming Indigenous community aspirations for language restoration and renewal in culturally coherent ways and self-determining directions. Centering the guidance, leadership, and modeling of Indigenous Elders by re-establishing traditional intergenerational relationships of knowledge production and exchange has had transformative results in places like Kanatsiowhareke Mohawk Community and the work of Mohawk Elder Tom Porter, who has played a critical role in the restoration, renewal, regeneration, and resurgence of the Mohawk language and culture (Holmes, 2018) of the Rotinonhsionni, the Haudenosaunee, or Iroquois Confederacy. The praxis of Elders nurtures Indigenous community language and cultural regeneration efforts, supporting and guiding their communities to reflect deeply about their process and practice, to (re)conceptualize what they are doing, what is important, and how to get there.

Indigenous language restoration, renewal, and resurgence

Restoring traditional Indigenous protocols, processes, and practices of relationality among the generations by placing them at the center of movements for cultural renewal creates resurgent possibilities for the re-awakening of languages. Indigenous language revitalization is reawakening as critical decolonizing work, as communities re-conceptualize and *re-contextualize* Indigenous language recovery, restoration, and renewal and how to go about it from within their own center, placed within their own longevity of contexts, experiences, and practices of meaning, memory, and intergenerational knowledge relations. Indigenous languages mediate an interweaving web of Indigenous worlds and relationships, systems of knowledge, thought, philosophy, ethics, and practice – ways of knowing and being – and it is this understanding that illuminates possible pathways toward the regeneration and resurgence of Indigenous languages, pathways that simultaneously awaken and invigorate Indigenous relationality, where these relationships are lived, known, embodied. Indigenous epistemologies and the lived, everyday practice of relationality are carried within the language in culturally meaningful, deeply contextual, placed ways.

As Indigenous communities revitalize their languages, they are restoring and renewing connections within *their own* places of power, knowing, and deep cultural coherence, looking to those places that have always offered their people clarity and resilience through an intimacy born of longevity and relationship with lands, waters, the natural world, Elders, Ancestors, future generations, collective narrative memory (McLeod, 2007), and the spiraling cycle of intergenerational relations. Remembering, re-imagining, and re-envisioning the ways Indigenous languages root and are rooted within their own relational universe readies the ground for intergenerational renewal and resurgence. In restoring and renewing the relationships between Indigenous People and their languages, lands, ways of knowing, and practices of the collective, re-weaving and re-presence-ing to intergenerational relationships of Ancestors and coming generations, remembering from within the praxis and teachings of Elders, an intricately interconnected matrix of relations is restored. Re-centering intergenerational relations as critical to the process of language renewal and the restoration of Indigenous 'language ecologies' ensures that Elders are placed once again in the center, embodying the reciprocity between the generations and the living of ancestral wisdom ... and holding the transformative possibility of guiding Indigenous languages into resurgence.

Indigenous language curriculum: issues and challenges

Indeed, "to find life" and understand its manifestations within each individual self is the ultimate goal of all education.

Cajete (1999, p. 60).

This section is written with Indigenous and non-Indigenous educators and stakeholders in mind, for all those who have an interest in understanding the complex genocidal history of Indigenous education (Skutnabb-Kangas and Dunbar, 2010). Similar to Indigenous Peoples around the world, experience of education was constructed from within a non-Indigenous system, in a non-Indigenous instructional setting, taught by non-Indigenous teachers, using non-Indigenous resources and curricula. The formal and hidden curriculum reinforces several primary themes: school teachers were non-Indigenous and resources were determined by non-Indigenous people. Hampton (1995) states, "For most Indian students, now as in the past hundred years, Indian education means the education of Indians by non-Indians using non-Indian methods" (p. 6). Indigenous Peoples worldwide have undergone similar educational experiences. From Finland, Russia, China, Africa, Australia, Hawai'i, New Zealand and the United States, Indigenous Peoples have been, and continue to be, subjected to systems of schooling that are determined by dominant governments, religions, or more populous national ethnicities (Smith, 2009). In spite of this, resistance by Indigenous minorities to teach their own knowledge to their children has never abated.

Despite Canada's longstanding attempts to separate and eliminate Indigenous families and communities from their children's education, Indigenous Peoples have challenged these attempts. Indigenous Peoples have stated that,

Unless a child learns about the forces which shape him: the history of his people, their values and customs, their language, he will never really know himself or his potential as a human being. Indian culture and values have a unique place in the history of mankind. The Indian child who learns about his heritage will be proud of it. The lessons he learns in school, his whole school experience, should reinforce and contribute to the image he has of himself as an Indian.

National Indian Brotherhood (1972, p. 9).

This statement suggests that Indian people be directly involved in the creation of school curriculum alongside the Canadian government.

Boarding or residential schools have also been implemented in many regions throughout the world, with differences depending on colonial context. Given the abject failure of residential schools of the 19th and 20th centuries, their operation today in similar institutions around the world is cause for concern. In India, for example, the Kalinga Institute of Social Sciences (KISS) is one of India's large scale tribal boarding schools, which contains striking similarities to the former residential school models that were

designed to remove Indigenous children from their families, languages, and cultural identities in Canada and the United States. Like the Indian residential schools in Canada and the U.S., at KISS,

...most children have to adapt to a new language, usually the dominant state language. Exclusion of tribal languages from most of India's tribal schools has contributed to the diminishing use of several hundred ancient tribal languages, which some scholars have termed 'linguistic genocide' in similar contexts. This is a tremendous loss in that each such language encapsulates a unique worldview.

Gupta and Padel (2020).

Although Indigenous educators around the world have faced great challenges, they have continued to develop language and curriculum from within their own contexts and communities, incorporating locally developed resources that reflect the unique languages and identities of their people. In Aotearoa/New Zealand, Maori communities and educators have asserted their self-determination to educate their children in Māori with the start of Kōhanga Reo or language nest preschools in the 1980s. On the heels of the Māori, and following the amendment of the Hawai'i State Constitution in 1978 which states that the "State shall provide for a Hawaiian education program consisting of language, culture and history in the public schools. The use of community expertise shall be encouraged as a suitable and essential means in furtherance of the Hawaiian education program" (Legislative Reference Bureau, 2022), a small group of educators and parents who made a commitment to revitalize Hawaiian founded the 'Aha Pūnana Leo—a non-profit Hawaiian organization. This was the beginning of the Hawaiian language revitalization movement that modeled language nest preschools after their Māori cousins. Formal education in both settings of Aotearoa and Hawai'i have included Māori and 'Ōlelo Hawai'i language which has extended from infant-toddler programs, preschools, elementary, middle-school, and high-school, and college, university and professional degree programs.

The exclusion of local Indigenous Peoples from institutions of public education as educators, administrators, curriculum developers and the like, remains one of the most challenging deterrents to the implementation of language and curricular resources in schools. The responsibility for locating, designing, and delivering quality curricular resources for schools is often given to classroom teachers, under the direction of regional and federal education mandates. Due to the already burdensome workload of teachers, it is untenable for them to undertake the creation of curricular resources, with the result being that the majority of teachers look for ready-to-use resources. This leaves centralized education authorities, institutions, and/or corporations to design and deliver curriculum. Those who are called to develop these resources often have no experience in creating curriculum, and are frequently unaware of whether the resources they create are culturally relevant or responsive. While faced with formidable challenges in designing and delivering quality language and curricular resources for their people, Indigenous Peoples continue in their efforts to teach their children their languages, histories, and identities. The settler-colonial model of education is generally acknowledged to have failed. Indigenous Peoples need to be able to chart their own educational path – and these paths continue to be embarked upon by Indigenous educators around the world.

Media and technology

"For Aboriginal/Indigenous communities, it has always been traditional to utilize the latest technology...

—Hulleah J. Tsinhnahjinnie (Seminole/Muskogee/Diné).

Incorporating technology to support new strategies that encourage everyday language use and the preservation of ancestral languages, as many Indigenous Peoples, communities, activists, and scholars will tell you, is not a new phenomenon. However, the perception of technology as a "cultural nerve gas" (Krauss, 1992, p. 6) in relation to minority or endangered languages has dramatically shifted over the last several decades to a more optimistic one. Hawaiian language activist Candace Galla (2016) asserts that it is difficult to envisage the "survival of Indigenous languages in the 21st century without the intervention of digital technology" (p. 1137). This change in perception in large part has to do with the innovative ways Indigenous and minority language speaking communities *themselves* are using technologies to strengthen their language and ancestral ways of being (Schwab-Cartas, 2018; Galla, 2018).

Potential benefits of technology are easy to imagine, but they also come with risks and challenges that need to be considered carefully. Of course, it is hard to be prescriptive about the drawbacks and benefits of technology, as what may work for one community may not work for another. The term technology itself "is actually quite vague and could refer to everything from hardware to search algorithms to data formats or user interfaces or many, many other things" (Hieber, 2015, p. 346). There are many devices and applications that fall under the umbrella of technology that are being used by Indigenous communities for language revitalization purposes. Some of the technologies that have been used range from wax cylinder recordings to "analog and digital video and audio recording devices, as well as a constellation of computer, mobile, and Internet related technologies [apps], to capture, store, and make available to future generations important aspects of their languages, arts, and understanding" (Oppenneer, 2011, p. 1).

Many of the technologies, apps and software being used to promote and foster Indigenous language learning are overlapping in capabilities and tend to work in symbiosis, so it can be very difficult to isolate them from one another (i.e., smartphones or tablets). Therefore, to be as clear as possible, we will use the helpful classification structure developed by Hermes et al. (2016), in order to

help the reader navigate the vast number of technologies, as well as to assist readers in determining options that might be the most useful and beneficial option for their language community. (It should be noted that as technology is rapidly evolving, it is possible that some of the technologies mentioned here, especially apps, may no longer exist at the time of publication.) The categories developed by [Hermes et al. \(2016\)](#) are as follows:

Documentation

Technology has been used for over a century to document and preserve endangered languages and cultures. This has included such things as the wax cylinder/mechanical phonograph, voice recorder, camcorder, computer, and mobile devices such as tablets and smartphones. Documentation was once thought to be an activity reserved for linguists or Indigenous communities with the “proper” equipment, but documentation has become a major social activity among everyday mobile phone users, especially youth, who tend to use mobile phones as personal mobile logs ([Stald, 2008](#)), recording via pictures (selfies), sound (audio recording) and video (Snapchat/Instagram/TikTok) their everyday experiences, whether watching a child’s first steps or an interesting event or recording an Elder speaking an Indigenous language ([Schwab-Cartas, 2016](#)). As many scholars have noted, documentation alone cannot save a language ([Hinton and Hale, 2001](#); [McIvor, 2009](#); [Perley, 2012](#)), but it can be a rich resource with which to develop curriculum and teaching materials, while fostering language transmission to future generations ([Littlebear, 1996](#)).

Language-enabling technologies

Language-enabling technologies, on the other hand, enable users to successfully communicate in their Indigenous languages via fonts, adapted keyboards, online dictionaries (from simple definitions to talking dictionaries), unicode, and even through culturally-rooted, culturally-significant emojis, such as Haida emojis. These technologies are typically created by communities, language activists, and/or linguists working alongside Indigenous speaking communities as a means of addressing the fact that most technologies, apps, and software are designed to support dominant languages, rather than Indigenous or minority languages. However, due to ongoing Indigenous language activism and its support in Indigenous communities, major software developers have taken notice. Apple, for example, has included Cherokee syllabary on all their iOS devices (iPads, iPhones, and iPods) since 2010 ([Kemper, 2015](#)). This is one of the many ways that Indigenous Peoples and communities, particularly youth, have found to address technological disparities, while adapting digital technologies and applications to make them relevant to their local communities and lifeways.

Information and communication technologies

Information and communication technologies (ICTs) are an expansive and broad category referring to interactive media ([Begay, 2013](#)), and include a host of various platforms, ranging from radio, digital technology, Email, and databases in the form of YouTube, blogs, and vlogs to videotelephony. ICTs are not specifically designed by or with Indigenous communities in mind, yet they are being used by Indigenous and minority language speaking communities in creative ways to support language learning and revitalization alongside language-enabling technologies. Radio, sometimes overlooked in the Global North, continues to be an important form of technology being used by Indigenous communities around the world, particularly in places where internet connection is limited. For example, radio continues to be used by Binni Cubi—a Zapotec media collective in Southern Mexico—as a cross-generational and affordable way to broadcast not only local community news, but promote Isthmus Zapotec language learning. More recently, due the global COVID-19 pandemic, many Indigenous communities have increasingly embraced video telephone platforms, such as Zoom, Skype, Facebook, and Bluejeans to connect with their communities and learn from Elders and/or fluent speakers.

Technologies that support language acquisition

Social media platforms

Language acquisition technology includes social media platforms such as FaceBook ([Cru 2015](#)), Twitter ([Lillehaugen, 2019](#)), Instagram ([Cassels, 2019](#)), YouTube ([Cru, 2018](#)), and TikTok ([Holmes, 2020](#)), to name a few examples, but it can also include the development and use of specific mobile applications for the purpose of language learning. Apps are now seen as part of a larger phenomenon known as mobile learning (M-Learning), which is a “new type of learning based on mobile technology where students can follow up their education *anywhere, anytime*, and in any *form* using their mobile devices” ([Mohanna and Capus, 2012](#), p. 315). M-Learning allows the user to obtain and/or provide pedagogical content that can be accessed on mobile devices, smartphones, iPods, and tablets ([MacEntee et al., 2019](#)). The pedagogical content of many of these apps includes quizzes that incorporate flashcards, phrasebooks, and talking dictionaries to teach and test vocabulary while the more advanced apps include speech detection software that test pronunciation. An example of these apps is the popular Duolingo, which includes global languages, such as English and Spanish, but has recently included endangered languages such as Cherokee, Hawaiian, and Gaelic. The advantage and benefit of this type of learning via an app is that apps are a great way “to jump-start learning, to reawaken what can be heard, to allow for private practice, to focus on particular confusing conjugations or to investigate unknown constructs or appropriate registers” ([Hermes et al., 2016](#), p. 276).

Technology as a double-edged sword: considering benefits and drawbacks

It is easy to get excited and want to use the latest technology; and yet, digital technologies can also be a double-edged sword. Along with the benefits, there can also be drawbacks that need to be considered carefully by the community, individual, or researcher. The following are several relevant issues to consider before, during, and after using technology. First, no technology is or can be a replacement for an Elder or direct, face-to-face, embodied engagement with a language or an ancestral practice. Technology is, rather, a supplementary tool. For example, an online dictionary app in an Indigenous language can provide the learner with a word, but only an Elder can explain its significance, illustrate the proper context in which it is used, and check the pronunciation of the word. Another matter to consider is rapid obsolescence of technology and apps—the rapid pace and change of technology means that developers and/or communities using technology cannot continually update their technologies or software. The sustainability of these technologies must be considered, along with whether the community has access to internet or sufficient broadband in order to run these websites. Another factor that needs to be considered carefully by each community is how to safeguard and protect itself from the risk of cultural/ancestral knowledge theft, appropriation, or disrespectful usage of sacred knowledge. Further concerns also include risks of screen time on younger children, or other concerns, such as cyberbullying or sexting (Shariff, 2015). This is by no means an exhaustive list of concerns, nor is it prescriptive; concerns will vary from community to community and context to context.

Collaboration, networking & resources: engaging in Indigenous language recovery, restoration, revitalization, and renewal

In this section, we share some resources from Indigenous Peoples, communities, and schools from around the world that can serve as guides as we engage in Indigenous language work. Whether you are just starting your language journey, are looking for resources to support your community, or want to learn from the experiences of other Indigenous Peoples who have found ways that have worked for them in recovering and restoring their languages, we offer examples from our lived experiences.

For many Indigenous communities, intergenerational language transmission has been disrupted, resulting in varying degrees of language loss, shift, repression, and shame. And yet, even with these external and internal challenges, individuals, families, and communities have continued to find ways to live their Indigenous languages by learning cultural practices, attending cultural events, speaking with Elders, accessing archived recordings, and so forth, collaborating within community and with other Indigenous communities and peoples. The exchange of knowledge and language reflects critical Indigenous principles and practices that continue to be enacted, where successes and challenges are shared, best and inspired practices are contemplated, and strategies that will inform our next plan of action are remembered and (re)imagined.

Learning from and through relational exchange

Indigenous Peoples have long navigated ancient pathways of interaction and exchange, forming bonds of relationship with each other across vast distances that are indeed, in the deepest sense, global and transnational. These relational, ethical practices of interconnection exist as a profound resource from which to draw strength, nourishment, and sustenance, as Indigenous communities (re)navigate these well-worn routes through the treacherous waters of settler-colonial narratives, home toward their languages. The interconnections and relationships formed between Indigenous communities have had important and meaningful impacts on language recovery, restoration, revitalization, and renewal. We highlight several examples of these relational exchanges of learning that have emerged between the following Indigenous language communities:

Mohawk and Hawaiian

Sister Dorothy Karihwénhawe Lazore (Mohawk) among others have been credited for bringing attention and greater awareness to the vitality of the Mohawk language in the community (Rice, 2019). Lazore, a first language Mohawk speaker, was instrumental in establishing the Kahnawà:ke Survival School that immersed children in the Mohawk language. In the 1980s, when 'Aha Pūnana Leo ('APL)—a non-profit Hawaiian organization—was in its early stages of setting up Hawaiian language immersion schools, Lazore appeared before the Hawai'i Board of Education to advocate on behalf of the Hawaiian program, which has now become a nationally and internationally recognized model for Indigenous language revitalization. In 2016, the founding members of 'APL, along with the Mālama Honua Worldwide Voyage crew, honored this long-standing relationship that spans nearly 5000 miles and 40 years of dedication, advocacy, and commitment to Indigenous language education.

Hawaiian and Blackfoot

In 1994, nearly a decade after the Hawaiian language revitalization movement and the opening of Hawaiian language immersion schools, Darrell Kipp (Pikuni), founder of the Piegan Institute (Kipp et al., 2015), traveled to a bilingual conference where he met Hawaiian language immersion educators and founders of 'Aha Pūnana Leo. According to Kipp (2000), "They were the first people we ever met who knew what we were seeking." (p. 8). He and other tribal members would visit Hawai'i that year to witness first-hand children speaking Hawaiian language, a great achievement, considering that a decade earlier less than fifty children under the age of 18 spoke Hawaiian as their mother tongue. Their visit allowed them to experience, learn, and ask critical questions of the Hawaiian language educators, and would be a source of inspiration for an all-day Blackfoot language program. Kipp (2000) states,

"The Hawaiians let us stay with them long enough until we felt we were ready. They let us write to them, and they called us when they knew that times were bad" (p. 40). He continues, "Today, we are the best of friends and would not be where we are except for their friendship ... They were mentors, our support, and our guides." (p. 8).

These knowledge exchanges among Indigenous Nations are two examples of the ways Indigenous communities have worked together to support each other in the regeneration of their languages and their goals of creating speakers in the community. Many local, national, and global relationships have been cultivated in the effort to share pedagogical practices, guiding principles, resources, tools, and struggles related to language learning and teaching. As Kipp (2000) states, "There are those moments when you think, 'All I need to do is talk to someone. I got to make sure that I run this past someone.' Know that we'd be happy to be that someone" (p. 40). Extended networks of Indigenous language communities enable collaborative possibilities in language development, programming, and policy, where communities are not forced to "reinvent the wheel" and invent ideas from scratch. By participating together and establishing relational networks, communities are able to maximize their resources, learning from each other what has worked (and not worked) in their respective communities, to help inform and develop their own vision from within their own community context and local needs, aspirations, and priorities.

Language learning

Finding speakers, resources, and materials by which to learn an Indigenous language varies from one language/dialect to another. For those who are (re)learning their mother tongue, there may be additional, very real barriers that discourage this process, such as personal, family, and intergenerational trauma, shame, and repression, as well as language policies and ideologies. For those on a path of language restoration and recovery, we offer some meaningful ways to jumpstart your language journey, whether you are embarking on an individual or family endeavor. Building on the legacy of the International Year of Indigenous Languages (2019), as declared by the United Nations, and moving into the Decade of Indigenous Languages (2022–2032), let us be encouraged by the language memories that might resurface and the language knowledge gained, as these become more familiar with time.

1. **Names carry power** – Introduce yourself and others using traditional and ancestral names. Learn those of others, and refer to each other by our Indigenous names. Encourage your family, friends, and colleagues to refer to you by your traditional name. These names carry your story, history, and connection to land/place. (Kaleimamoowahinekapu)
2. **Positionality** – Learn how to introduce yourself and describe your relationships to people, land, and the more-than-human in your language. This can include your genealogy, traditional lands, waterways, and mountains. ('O Candace Kaleimamoowahinekapu Galla ko'u inoa. He Hawai'i au. *My name is Candace Kaleimamoowahinekapu Galla. I am Hawai'i/I am Hawaiian.*)
3. **Salutations** – Say your greetings and farewells, and use appropriate responses to each other in the language. (Aloha nō! Pehea 'oe? *Hello! How are you?*)
4. **Social Interactions** – Begin in-person, face-to-face, and digitally-mediated interactions in the language. Answer and end the phone call in the language. Record your voicemail greeting/message in the language. Begin and end your emails, texts, or chats in the language.
5. **Interior Design** – Consider writing words, common phrases, and actions on labels to display them in places that are occupied or frequented (for example, the kitchen, living room, office). Replace the labels with new ones as these words and phrases become a part of your lexicon and your vocabulary expands.
6. **Language domains** – Identify specific spaces or rooms in your home, frequented spots, and/or commit specific times in which you will spend immersed in the language (for example, at breakfast, on car rides, on the way to/from school or work).
7. **Cultural practice(s)** – Identify your favorite cultural practice or activity and learn words, phrases, and cultural protocols that are relevant to it. Use this vocabulary while engaging in the practice, and use it with other cultural practitioners and knowledge holders.
8. **Task-based activities** – Choose a task (for example, cooking, weaving), and learn how to complete the task in the language. Make this a part of the weekly schedule so that it becomes a customary practice.
9. **Song and Dance** – Learn songs, chants, and prayers in the language. Learn what is being expressed by the lyrics and be taken on a journey to experience the story. Or better yet, write your own lyrics, sing them, dance, and create choreography to the lyrics – share them!
10. **Other companions** – Speak to your pet(s) in the language. Most don't speak back, so try your language on them. They are great listeners and don't judge you!

Each of these practices can be adapted to work with language learners and speakers at any level. Whether you live in community or now reside in the big city or a different country, find language resources (speakers, books, media) to help support your journey. Remember to recognize, celebrate, and reward your progress, small and big. Safeguard Indigenous languages, protect these language spaces, and encourage others to join your movement with the intention to build language capacity so that we use Indigenous languages in all domains.

And most importantly, have fun – enjoy learning and speaking your Indigenous language! Through our ancestral languages, we begin to understand our relationships with and responsibilities to each other and our natural environment, which will guide us to a healthy and sustainable future.

With idea, sound, gesture, the duende delights in struggling freely with the creator on the edge of the pit ... the duende wounds, and in trying to heal that wound that never heals, lies the strangeness, the inventiveness of a man's work.

... We have said that the duende loves the edge, the wound, and draws close to places where forms fuse in a yearning beyond visible expression.
Lorca (1933).

Scientists, linguists, philosophers and poets alike stand in awe and wonder at human language and the capacity for creativity and inventiveness in all its expressive communicative forms. From the vastly studied origins of human language, to the unending genesis of new languages (Riley, 2015), new language varieties (Mufwene, 2008), new styles (Eckert, 2012), new repertoires (Blommaert, 2010; Nassenstein and Hollington, 2016), and new modes of multimodal communication (Hollington and Nassenstein, 2018; Riley, 2015), this artful generativity both marks and is marked by emerging speech communities continuously creating and recreating individual and group social political identities. This deep, innovative, creative ability endlessly generates new ways to symbolically communicate our humanity through a vast range of fluid expressive forms, linguistic and communicative resources and artful performative practices. From individual's daily novel utterances, to newly emerging lexical and syntactic forms, language births, and original innovative multimodal communication systems, language never sits still. Even a child's language development and acquisition has been more aptly described as a process of continual language invention (Gleitman and Newport, 1995). Language is always changing; always dynamic; always newly performed, played with, invented, created, manipulated, (re)shaped, refined and reconstructed. It is always “language-in-motion” (Blommaert, 2010, p. 5). This fluidity describes “the shifting and ever-changing linguistic material, the ways this material is used by speakers, the speakers themselves, their social and cultural environments, people's identity practices, etc.” (Nassenstein and Hollington, 2016, p. 183).

Understanding its everchanging nature, Garcia and Wei (2014) prefer to use the verb “languaging,” introduced by Becker (1995) in his work with translation, rather than the noun “language.” They write,

... languaging is a better term to capture an ongoing process that is always being created as we interact with the world lingually. To learn a new way of languaging is not just to learn a new code, [...] it is to enter another history of interactions and cultural practices and to “learn a new way of being in the world” (p. 8).

They see language as “a set of resources, language ideologies and social constructions, the multimodality of communication among others” (p. 8).

In this essay, we favor the dynamic, complex and socially embedded view of language as always being invented, always in process, always meaning making, and always in context. Further, we recognize the esthetic, performative, emotive, relational, playful, multimodal and artful aspects of languaging too often ignored by linguistic studies that focus purely on language form and

structure. Influenced by and extending the work of Gilmore (2016, 2017), we view human language creativity in all its multimodal dynamic semiotic forms and communicative performances, as embodying what the poet Lorca (1933) describes as the miracle of the *duende* which he sees as the source of all “newly created things.” Gilmore (2016) writes,

Federico García Lorca ... has captured the mystery of the phenomenon of the creative process most profoundly. In his classic essay, *Theory and Play of the Duende*, based on a lecture he delivered in Buenos Aires in 1933, Lorca described the *duende* as the power and struggle of spontaneous creation, as a “burst of inspiration, the blush of all that is truly alive, all that the performer is creating at a certain moment.” Lorca writes, “The *duende*’s arrival always means a radical change in forms. It brings to old planes unknown feelings of freshness, with the quality of something newly created, like a *miracle* (emphasis mine).” ... In Lorca’s original lecture, he referred to the thousand boring lectures he attended in his studies in Madrid that made him “hungry for air and sunlight” and “covered by a light film of ash.” Instead of the intellectual rationality of scholarship, he turned to the *duende* to explain the unexplainable about the art of creation. He describes the *duende* as “a mysterious power which everyone senses but no philosopher explains” ... It is a heightened state of human reality with all its joys and sorrows, of spine-chilling authenticity The *duende*, especially associated with the evocative aesthetics of flamenco and the bullfight, has also been invoked to both inspire and explain a range of modern art forms in music, painting and poetry (pp. 55–56).

Lorca’s (1933/1998) notions of the *duende*, unlike the romantic inspiration of the angel or muse, depicts the dark ongoing struggle that both hurts and attempts to heal. Lorca writes, “With idea, sound, gesture, the *duende* delights in struggling freely with the creator on the edge of the pit. Angel and Muse flee, with violin and compasses, and the *duende* wounds, and in trying to heal that wound that never heals, lies the strangeness, the inventiveness of a man’s work” (p. 67).

In this essay provoked by the concept of the *wound that never heals*, we draw on Lorca’s notions of the miracle of *duende* to explore the creative processes in each of the illustrative communicative examples we present. We have selected three disparate examples of this dynamic communicative creativity and semiotic language innovation. In each of our examples, we highlight and extend Lorca’s conception of the *duende* by exploring themes of struggle with colonial oppression and a range of attempts to heal its injustices through newly creative human expressive forms. While Lorca focused on the inventiveness of the individual creator—the artist, the poet, the musician, the dancer—this discussion will extend the reach of the *duende* to examine collaborative, collective, and community communicative creativity and innovation. These social interactive creative processes demonstrate a significant layer of human inventiveness where the group or community—rather than an individual—comes together to struggle with the *duende* in order to generate a dynamic innovative capacity in the face of oppression and injustice. Further, we extend Lorca’s discussion of the *duende* by exploring the significant role play, humor, satire and irony can serve in creative resistance to oppression (Vizenor, 2008; Deloria, 1969; Bresnick, 2019; Gilmore, 2016; Wyman, 2012). Often, the “fueling of innovation” (Kahaunalele, 2020) can find its source in the struggle to *heal that wound that never heals*. The three stories that follow demonstrate *just* ways of creative *languaging* that resist and critique oppression, renew agentive identities, and establish community solidarity in the face of settler colonial injustice in Indigenous contexts. While an abundant range of artful creative expression is inspired by existential reflections about joy, love, birth, despair, grief and a myriad of other profound human life experiences, we focus exclusively on the inventiveness evoked by the wounds of, and resistance to, colonial domination, oppression, and injustices. Through pain, joy, humor, play, verbal art, dance, song and digital expression, each case dramatically calls out for *just languaging* with evocative spirit and social *duende*.

The first narrative describes the case of two 5-year-old boys, one white American and one Indigenous Samburu, who met and became inseparable friends on an isolated hillside in rural Kenya in 1975. Their controversial postcolonial relationship was created through and marked by their invention of *Kisisi*, an original Swahili pidgin that was understood and shared by just the two of them. Their irrepressible linguistic playful creativity creates a space for their friendship that transcends the existing language ideologies, marked colonial borders, and harsh inequities of economics, race, and settler colonial culture that engulfed all aspects of their daily lives (Gilmore, 2009, 2011, 2016).

In the second example, we examine the collective languaging and expressive practices of an Indigenous movement space (Eagle Shield et al., 2020; Paris, 2019), where we witness the creative mixture of enduring languaging in hula and mele that expresses collective life force, *duende*, and power in a struggle to protect sacred land during the current Hawaiian Renaissance. Traditional and contemporary practices of hula and mele, their intersections and cross-currents, meanings and poetics are explored through its innovation and inventiveness in response to controversial contemporary injustices despite pressures within and outside the community to conform to Western ideologies (Galla et al., 2015).

Drawing from anticolonial work with Indigenous literacies and creative writing, and holistic pedagogies (Horner et al., 2021; Muñoz, 2020), the third example explores Indigenous language practices and social media, largely influenced by youth, as an artful driving force in communicative practices that create digital spaces as sites where “new creative practices arise, are negotiated and serve as identity markers across widespread digital communities ...” (Hollington and Nassenstein, 2018). These transidiomatic practices (Jacquemet, 2005) are new forms of communication and new mediatized spaces (e.g., Facebook, Youtube, TikTok, Twitter, WhatsApp), with mobile people and mobile texts, that allow new syncretic ways to foster relationships and stay bonded across previously vast translocal life distances. These creative new communicative repertoires and codes include, and are a part of broader stylistic, esthetic, poetic, emotive, playful, humorous, satirical, and agentive choices that are strategically navigated in order to perform changing identities, assert sovereignty, affirm community, and enact collective resistance in the face of colonization and oppression (Gunn Allen, 1986; Berglund and Carlson, 2020; Gilmore and Wyman, 2013; Riley, 2015; Wyman et al., 2013, 2016).

Kisisi: young children invent a Swahili pidgin in rural Kenya

In this section, we highlight the unique processual documentation of the birth of a private language invented by two 5-year-old boys, Colin and Sadiki, who in 1975 by chance became neighbors and inseparable friends for 15 months on a remote and isolated multilingual hillside in postcolonial Kenya. Perry Gilmore, one of the authors of this essay and Colin's mother, describes these events in detail in her book, *Kisisi (Our Language): The Story of Colin and Sadiki* (2016). In her ethnography, she explores (1) the awe and mystery of the children's new language creation; (2) their agentive socio-political linguistic resistance to oppressive settler colonial language regimes, ideologies and policies; and (3) the evocative *duende* embodied in the verbal art, play, and performative transcendent healing power of their language use in this overtly harsh and racist context.

Colin, an English speaker, was the son of American researchers studying a troop of wild baboons. They lived in a research residence located on a 48,000-acre cattle ranch owned by a prominent settler colonial family. Sadiki, a Samburu speaker, was the son of Indigenous Samburu ranch workers who herded cattle on foot for meager wages and lived with their five children in small cramped laborer's quarters just yards away from Colin's family. Additional ranch workers from different tribes also lived on the hillside in workers' quarters. All social interactions between the residents in this multilingual contact zone were conducted in Swahili, the local lingua franca that held a dramatic history as a tool of colonial domination and power (Fabian, 1986; Gilmore, 2016; Myers-Scotton, 1978; Ndege, 2009; Skutnabb-Kangas, 2011). Swahili was the language of the dominant colonial enterprise. It was the language the colonials used to give orders to workers. It was not the language of personal relationships. Yet the boys were expected to use Swahili in all of their interactions. Instead, as the boys played together, they created a shared language that sounded Swahili yet was unintelligible to Swahili speakers. Their language, Kisisi, displayed characteristic features of pidgin, creole and emerging languages all over the world. These translanguaging practices (e.g., see García and Wei, 2014; Nassenstein and Hollington, 2016) are common in multilingual contact zones and have recently received much attention in discussions of superdiversity (Blommaert, 2010). However, the degree to which they expanded and elaborated their language was unique, especially for such young children. Their language invention demonstrates striking linguistic and sociolinguistic competencies of very young children who are too often highly underestimated in this regard. As these young boys playfully negotiated diverse linguistic ecologies and cultural spaces, they displayed abilities as highly effective language innovators creating a unique language with sophisticated original phonological, lexical and syntactic features (see Gilmore, 2011, 2016 for further discussion of these features).

The language

Kisisi shared many characteristics of pidgin languages all over the world. Pidgins arise in extended contact situations where individuals have no common language and develop a means of restricted communication that serve their limited needs. Extended language contact typically arises in a range of circumstances including "discovery," trade, conquest, slavery, migration, colonialism and nationalism, to name a few. Many of these contact conditions have historically marked unjust, often cruel and unequal power relationships. No one's first language, pidgins are characterized as simplified contact languages having pared down many of the inessential features of the different input languages. This simplification process is similar to the linguistic accommodation that occurs in a number of other linguistic circumstances where individuals do not share the same language competencies.

Gilmore (2016) found that the language shared the classic pidgin features including—a restricted lexicon, absence of articles, markers, inflection and copula (i.e., the verb to be), preverbal negation, polysemy (i.e., many meanings for one word), and circumlocution (i.e., figures of speech), to name a few. This finding was striking because it countered the pidgin/creole literature that claimed children learn pidgins from adults. Kisisi is a vivid example of children creating a pidgin rather than being taught by, or learning a pidgin from, adult speakers.

As the months passed, the boys' language began to exhibit characteristic features of more lexically and syntactically complex creole languages. Where a pidgin functions to serve limited language contact needs, a creole serves as a primary language in a speech community. As the creole process progresses over time, the original pidgin will undergo change in response to the growing needs of its speakers to communicate about a full range of human experiences with a richer lexicon and more grammatical complexity.

In Sadiki and Colin's language, there was a constantly expanding lexicon incorporating many new loan words, metaphoric compounds, and numerous neologisms (i.e., new words). Original articles, pronouns, and novel tense and aspect markers were introduced. All of these features are typical of elaborated creole languages rather than simplified pidgins. Creoles are used by large populations across multiple generations before accomplishing such language innovations. It is remarkable to discover two 5-year-old boys effectively creating and creolizing a pidgin in less than 15 months. An additional assumption in the creole literature is that adults are the innovators and children are characterized as the regulators. In this case, it is evident that the children were the innovators!

An illustration of their metaphoric creativity can be seen in the modification of several Swahili loanwords the boys combined to create new meanings. This process of "calquing" or compounding generated poetic imagery and lexical invention. For example, the Swahili word for sun is *jua*. Compounding two different Swahili words, the boys instead called the sun *kubwa moto* or *big fire*, displaying their rich metaphoric inventiveness. The word *choo* in Swahili has multiple meanings. It can refer to feces, urine, or the lavatory itself. The boys especially delighted in elaborating, over expanding and playing with their lexicon for toilet activities—often accompanied by farting noises and hilarious laughter. By compounding the Swahili word for water (*maji*) with *choo* (feces), they distinguished urinating (*maji choo*) from defecating (*choo*)—a significant and highly entertaining scatological distinction for 5-year-olds.

They also generated novel syntactic structures to express tense and aspect. For example, they created an original future tense marker by positioning the Swahili verb *kuja* (to come) as an auxiliary before the main verb. For example, “Mi *kuja* run” means “I will run.” The verb *kuja*, used as a newly invented future marker, was pragmatically helpful, enabling the boys to distinguish between play actions happening in the present, and imaginary future actions they were planning in their pretend play. They also used the Swahili verb *enda* (to go) as a preverbal auxiliary to mark on-going durative and iterative action as distinct from punctual action—allowing them to distinguish between someone shot dead on the spot, from someone dramatically dying slowly over time. The boys also introduced novel forms of articles, pronouns and markers. One fascinating example was their use of the Swahili word, *moja* (one), to function as a pronoun and an article. For example, they would say “*moja* road” for “the road.” Or they would refer to an individual thing or person as “*moja*” saying “*tagid moja*” or “take one.”

These examples of invented linguistic forms and structures of Kisisi demonstrate that 5-year-old children can and do understand and generate sophisticated grammatical functions and syntactic complexity in ways that our standard kindergarten curricula clearly do not recognize, and drastically underestimate.

Symbolic performances and semiotic resistance

The symbolic sociopolitical metacommunicative aspects of the performances of their language were also profound. The children’s vast differences in culture, race, and economics made their friendship highly controversial given the settler colonial socio-political ideologies and power hierarchies of the period. Yet despite these circumstances, Colin and Sadiki’s transgressive border crossing friendship grew into an intimate bond created through and marked by the invention of Kisisi. Their language helped them construct new identities, resist, transgress, transform and heal the marked colonial borders and harsh inequities that engulfed them and marginalized and excluded Indigenous Africans.

Colin and Sadiki’s isolated and remote rural situation contributed to their language innovation, collaborative language choices and social practices. By choosing to sustain, expand and develop their own private language, they resisted the dominant language ideologies that represented the hegemonic, racialized, postcolonial order of the newly independent Kenya. Their public use of their private language was their cultural critique of an oppressive regime in which their own cross-racial friendship was considered by many as a violation of social norms. The boys refused to docilely participate in the existing colonial order and rejected the Up-Country Swahili language that was designed and designated to keep that order, and the Indigenous population, in place. They resisted being socialized into a language ideology they rejected, and instead created a new language ideology that allowed a safe and celebrated space for their friendship. Their effective, border crossing agency was accomplished through loving verbal art and euphoric play. Their joy filled language practices challenged the oppressive colonial culture that surrounded them, identifying them as a distinct and separate speech community that valorized its own social justice values and allowed a space for their friendship.

Sadiki and Colin’s language began in response to a pragmatic need to understand each other in order to be playmates and friends. Their early genesis of an original, simplified Swahili pidgin served that immediate function, facilitating their play and budding friendship. As time went by and their close bonds deepened—even as Sadiki learned enough English and Colin enough Swahili to switch to using either of those languages—they continued to use, play with, expand and creolize Kisisi. Both English and Swahili signaled colonial power hierarchies and racial stratification that were inappropriate for two close and equal friends. Instead, Kisisi created a separate and just universe that allowed them to escape the unjust colonial order. Kisisi was fun. It was secret. It was theirs. It was an artistic verbal spectacle that surprised and captivated unsuspecting audiences. Their new language bonded them as much as it reflected their bonds. Through their language use, they carved a new exclusive and symbolically resonant healing space, a separate and safe universe for their friendship. Sadiki’s family saw the language as a gift from God, *Mungu*, because, as Sadiki’s mother said, “He saw how much they loved each other.” Seen as a sacred blessing, Kisisi carried a special spiritual evocative semiotic message, touching witnesses in a deeply emotive healing way. To mark this special spiritual bond, Sadiki’s grandfather traveled for miles from the Samburu Reserve to conduct a special ceremony making Colin Sadiki’s brother and one of their family.

Their wild-tongued (Anzaldúa, 1987) playful yet hegemonic defiance and social transgressions disturbed and disrupted racialized and strictly segregated postcolonial spaces. Where these ruptures occurred, the children opened spaces not only for themselves but for others whom they touched and changed by their friendship. Their newly created, ludic, and passionate communicative practices became a form of healing discursive “parrhesia,” a means of speaking truth to power, that confronted, transcended, and in some small ways transformed the harsh and brutal colonial world in which they lived. Their invention of Kisisi enabled them to question and challenge the hegemonic settler colonial ideologies and racist identities that attempted to define them, separate them and squelch their precious relationship—their *wound that never heals*. Their hybrid anti-language reflects their intentional revoicing of cultural elements and describes a process of ludic creativity that dialogically manipulates language, culture and identity for them and for others who witness and interact with them in their creative linguistically carved liminal, in-between, and subversive space. We see both Sadiki and Colin together, struggling with the *duende* on the edge of the pit, as they try to “heal the wound that never heals” with their risk-taking border crossing language practices—their creative languaging for moral justice against oppressive and persistent colonial powers.

Fueling innovation: bringing forth embodied language practices

From the onset of European colonization, raciolinguistic ideologies played an integral role positioning Indigenous Peoples in Africa, the Americas, and beyond as less than-human to justify projects of slavery and annihilation. Seen as the “Indian Problem,” Indigenous Peoples continue to be targeted in an effort to be extinguished and “absorbed into the body politic.” (Scott, 1920, p. 55 (L-3) & 63 (N-3)). As evidenced by the very existence of Indigenous Peoples today, the genocidal practice upon Indigenous bodies, hearts, spirits, and minds were not successful. Despite settler colonialism’s desire for assimilation, the prohibition of linguistic and cultural practices, the lived experiences and current realities as a result of forced removal and relocation, and other related oppressive systems, Indigenous Peoples have not only demonstrated resilience and survivance (Vizenor, 2008), but “thrivance.” Enacting thrivance calls for a resistance, perseverance, and endurance that looks toward an imagined, flourishing Indigenous future and healthy community. Through the reassertion of sovereignty and self-determination, Indigenous Peoples, communities, and nations have championed community-led and -centered initiatives, educational programing, and capacity building to effectively “break the chains that bind us to our colonial existences” (Alfred and Corntassel, 2005, p. 613). While Indigenous language transmission has been disrupted for generations, Indigenous Peoples throughout the world, are reaffirming their inherent human rights to protect their knowledges and languages from further desecration, exploitation, and commodification. The activation of “being Indigenous means thinking, speaking, and acting with the conscious intent of regenerating one’s indigeneity” (p. 614)—which includes the “maintaining of the tradition and the fueling of innovation” (Kahunaale, 2020, p. 541) through linguistic and cultural practices. One such exemplar that demonstrates innovation and inventiveness includes the recent creative contributions made by Kānaka Hawai’i specifically (and other cultural practitioners generally) who embody mele (song) and/or hula (dance) through ‘Ōlelo Hawai’i (Hawaiian language). While this section speaks of Hawai’i and Hawaiian language, the examples discussed may have applicability and similar pathways that parallel the experiences of other Indigenous nations, communities, and peoples. The struggles, challenges, opportunities, and successes are what binds us together. The illustrations described acknowledge, demonstrate and document language inventiveness that has been inspired by activism, sacrifice, and protection of Maunakea—also known as Mauna a Wākea—a sacred place/being that is significant to Hawaiian identity, well-being and security (Kānaka’ole-Kānahele as cited in Kumu Pono Associates, 1999).

The Thirty Meter Telescope (TMT)—a \$1.4 billion project—has garnered local, national and international attention as the largest telescope in the world to be built, in a location on Hawai’i Island that would further destruct and desecrate the living entity and deeply rooted spiritual connections to Hawaiian knowledge systems. The connection that Kānaka Hawai’i have to Maunakea can be appreciated and understood similarly by the relationships that peoples and communities have to their sacred lands—to name a few—Bears Ears (United States), Kaya Forests (Kenya), Uluru (Australia), Machu Picchu (Peru), Mount Fuji (Japan), and Mount Sinai (Egypt). More specifically, Whanganui River (New Zealand), Muteshekau Shipu (Canada), and Klamath River (United States) are natural landscapes and resources that have been granted the same legal rights as a person, thereby recognizing that the guardians of these sacred spaces will maintain their health and well-being according to specific local traditions and customs.

Though Maunakea has not yet been granted the same legal rights as a person, the Protect Maunakea movement has galvanized a present-day rebirth, restoration, renewal, resurgence, reclamation, and recommitment to Hawaiian ways of knowing, being, and doing—nearly 50 years following the Hawaiian Renaissance that propelled Hawaiian language medium education. This education in Indigenous movement spaces (Eagle Shield et al., 2020; Paris, 2019) has (re)activated the desire to (re)learn traditional practices grounded in Hawaiian epistemology that (re)ignites the flame within youth, adults, Elders; individuals, families, communities, diaspora, and beyond. Supporters near and far demonstrated support, aloha ‘āina and kapu aloha to Maunakea in various ways that include: witnessing, learning and participating in cultural protocols, mele and hula—through in-person visits and/or virtual engagement, attending community-led classes and university-credited courses on the mauna, sharing news and updates via social media using relevant hashtags, writing advocacy letters urging for the divestment from the TMT project, (re)familiarizing old and introducing new mele honoring Maunakea, and a virtual worldwide jam.

Some of these embodied and performative expressions have been passed down through generations retaining the same cadence, rhythm, style, sentiment, and/or gestural and foot movements, while others may have changed ever so slightly, or renewed, (re)created, and (re)imagined to depict the current contexts and realities. What remains consistent is the language—the lyrics of the mele which reveal just one layer of the Indigenous storywork. These documented and lived practices—preserved instances of oral and embodied practices—are demonstrations of genealogy(ies) of language and cultural practitioners who have resisted oppression and made concerted efforts to carry forward Hawaiian traditions and customs.

(Re)activating and (re)centering language in/to cultural practices

Hula is a traditional dance—an evolving tradition (Silva, 2014) of Hawai’i that requires a mele (song)—that is now practiced, learned, and taught to students of all ages and cultural backgrounds, not only in Hawai’i, but in many parts of the world (e.g., USA, Canada, Japan, Mexico, Australia, France, Germany, Nigeria, Tahiti). Unknown to many, Hawaiian language is the essence of hula that presents a window into the culture. “Hula is first a language that has a choreographical piece to it” (Taupōuri Tangaro as cited in Smithsonian, 2013, 0:39) that requires the living flesh to interpret it with truth (Lorca, 1933). However, due to the illegal overthrow in 1893 by the United States, along with a language bill HRS 298-2 in 1896 that prohibited Hawaiian language medium

instruction, many Kānaka Hawai'i did not grow up learning the language. The disruption of intergenerational knowledge and language transmission also applied to cultural practices like hula.

Fortunately, the Hawaiian language is being actively revitalized through community initiatives, school programing, and family and individual commitment, and is making an incremental return. Hula and mele are just some of the ways that Hawaiian language is being amplified. A concern, however, of this now globalized art is that the expansion of hula beyond Hawai'i and the plethora of digital technologies has resulted in learned choreographies that are mechanical in form, rather than a deep, heart learning and embodied understanding of the story that is based in language.

The Hawaiian language composed poetically and presented melodically in mele, carries the meaning in the art. Hula without the conventional use of its characteristic Indigenous language would not exist as a specific art form. The language encodes the values and knowledge of the Hawaiian people in a unique cultural way of being. As hula is learned and performed in many places outside of Hawai'i, it reinforces the importance of Hawai'i remaining true to the substance of hula's personification through its own Indigenous language.

Galla et al. (2015, 130–132).

It is even more critical now to (re)activate and (re)center Hawaiian language into hula to understand that hula is much more than entertainment and is not a stand-alone performative art that is void of language and culture. Not only is hula a site of linguistic memory, but “is inherently a site of cultural memory, not only in the act of performance, but in the entirety of its practices of archiving knowledge” (Stillman, 2001 p. 188) that endures generations—past, current, and future.

Along with this renewed energy to recover and reclaim mele and hula, cultural practitioners are creating new compositions and choreographies to employ activism and to document important events and lived experiences (Kahaunaele, 2020). This has resulted, for example, in mele from the Kūha'o Maunakea album that document and depict the reciprocal relationship that Kānaka Hawai'i have to Maunakea and vice versa, and hula that is choreographed to chronicle, personify, and illustrate a specific event, experience, emotion, and/or spiritual connection. These linguistic, literacy, and literary practices are forms of education that have adapted to the changing contexts of Kānaka Hawai'i who are creating new opportunities for language use for learners/speakers from newborns to elders. These multimodal opportunities ensure that there is thriving, cultural continuity and intergenerational knowledge transmission that responds to the needs of the diverse community that extends from Hawai'i born Kānaka Hawai'i to diaspora, and beyond.

Mele and hula as embodied calls to action and solidarity

Candace Galla, one of the authors of this essay recalls the summer of 2019, when there was a heightened awareness and tension regarding the TMT. Some of the poignant memories include livestreams of the arrests of kūpuna (Elders) who blocked the road to the summit of Maunakea in protest of TMT construction, and in protection of Maunakea, and the cutting of the hae Hawai'i (Hawaiian flag) by a law enforcement officer. Though she would bear witness through a laptop screen of her birthlands, she would engage in the mele and hula that kia'i (protectors) at Maunakea were leading. She had learned some of these mele and hula decades before by virtue of growing up in Hawai'i, being raised in a hula family, and learning 'Ōlelo Hawai'i. However, some of these mele were newly written, created, and composed as a way to respond to and document the change in tide that would live forever in the physical bodies, spirits, and virtual elements and realities, while contributing to an archive of embodied language practices.

Familiar language expressions were a comforting blanket, while new language phrases describing a not-so-foreign event of blatant disregard of Indigenous rights was met with hope and a desire to articulate and embody newly constructed mele that would resonate in the hearts of Kānaka Hawai'i, Indigenous Peoples, and allies across the globe. The recitation and invocation of mele summoned individuals, communities, and nations to stand in solidarity with Maunakea, while also calling upon ancestral genealogies and the more-than-human to witness, protect, and safeguard Maunakea and those kia'i who have taken on the privilege and responsibility to care for Maunakea.

One such mele that garnered attention was a collaboration between cultural practitioner Hinaleimoana Wong (also known as Kumu Hina) and musician Josh Tatofi—For the Lāhui (For the Nation), which was inspired by Tatofi's visit to Maunakea. This mele begins with describing the beloved flag waving high in the sky, calling on the lāhui to be bold, fearless, and steadfast, and ends with the words articulated on July 31, 1843 by Kamehameha III—Ua mau ke ea o ka 'āina i ka pono (The life of the land is perpetuated in righteousness)—which calls into memory the restoration of the Hawaiian kingdom following a 5-month long British occupation. The lyrical notes of this mele for this noted phrase—which is used as part of the State's motto—calls “[f]or the freedom of our land remains always in the truth of our people,” in turn giving strength and hope to Kānaka Hawai'i. The official music video included footage—a montage of photos and videos in black and white, and color of kia'i, kūpuna, community, law enforcement—capturing the sentiment, emotion, and connection to Maunakea, and documenting the continued occupation, injustice, and arrests. This mele inspired hula practitioners, like Galla who resides in Canada, to create new hula choreography that would be shared in-person and virtually in the United States, Canada, and Australia as a way to heal her wounds and to stand in solidarity with kia'i on Maunakea and other sacred lands that are under siege.

At and for Maunakea, mele and hula were used to invigorate and diffuse (Kahaunaele, 2020)—to resist, to energize, to empower, and to heal. A combination of old and new mele and hula graced the mountain in response to the violent acts which would be livestreamed for the world to see and experience. These intended and embodied expressions are examples of how Kānaka Hawai'i are continually languaging while acknowledging, respecting, and staying true to dynamic and cultural traditions.

Inventive anti-colonial Indigenous social media

Through wide-ranging, fluid expressive forms, Indigenous Peoples are resisting settler colonial violence and remaking representational politics, communicating humanity and community-building with inventive social media. Indigenous erasure, stereotyping, and misrepresentation in media naturalize colonial logics and “cycles of bias” that continue to harm Indigenous Peoples (Eason et al., 2018, p. 70; Meek, 2020). However, Indigenous influencers are showing Indigenous resistance, survivance, and thrivance through digital blogs, podcasts, arts, news, hashtag activism, research, and media movements. Related transidiomatic practices amplify Indigenous voices and engage publics in “changing the narrative,” about Indigenous Peoples to “reclaim Native truth,” (Reclaiming Native Truth, 2018; National Council of American Indians, 2019).

In 2020–21, alongside racial turmoil, violence, and COVID-19 pandemic devastation in Indigenous communities, we witnessed an explosion of Indigenous inventive languaging practices across social media platforms, in spite of entrenched digital divides (Howard and Morris, 2019). Two illustrative examples, discussed below, generated widespread vibrant expressions of heart and spirit among Indigenous communities in 2020–21, illuminating language creativity and *duende*.

Something Else

In the 2020 US elections, in spite of suppression and misrepresentation of Native American votes, grassroots mobilization and record levels of voter turnout in Native Nations strongly influenced voting trends and historic wins in national, state and local elections. Few news correspondents, however, mentioned Indigenous voters when reporting Presidential election polling data. Insultingly, CNN lumped together multiple non-white voting groups, including Indigenous voters, under the dehumanizing label “Something Else” (Native American Journalists Association, 2020). This erasure prompted a cascade of widespread critique and commentary by Native American, Indigenous and other communities across digital platforms.

For example, in an episode of *Natives React*—a YouTube vlog focused on Indigenous media and news—co-host Patrick Willie, a Navajo YouTube influencer, summed it up:

Guys welcome back to another episode of *Natives React: Something Else*, Natives. And what does that even mean? So basically, during this election time, CNN, they put up a graph detailing the different races that had gone through the exit poll. They broke down the race by white, Latino, Black, Asian and then Something Else [...] every Native American was talking about this being labeled as Something Else.

Patrickisnavajo (2020b).

Indigenous laughter and jokes have long affirmed solidarity within and across Indigenous communities, while countering “the horrors of history,” “the continuing impact of colonization,” “the biting knowledge that living as an exile in one’s own land necessitates,” and “shabby and tricky” offerings of the contemporary world, “that needs to be treated with laughter and ironic humor” (Gunn Allen, 1992, p. 158). Online, Indigenous content creators circulated humorous and serious memes, videos, and commentary to address this newest form of erasure, anti-Indigenous racism, and settler colonial equivalency lumping Indigenous Peoples with other marginalized groups (see Tuck and Yang, 2012).

Multiple content creators posted humorous Something Else TikTok video sketches. An example from Brett Mooswa, a Makwa Sahgaiehan First Nation influencer, starts as Mooswa completes a joke to someone offscreen left:

“So I says to Roger, you can’t put milk in it, it’s not even a cereal” [laughing]

An unseen speaker (also Mooswa) interrupts from offscreen front, asking in a high, tentative-sounding voice:

“Excuse me, are you Native American?”

Clearing his throat, Mooswa puts on a severe, “Hollywood Indian,” Richard Curtis photograph expression. Staring up into the distance, he answers in low, slow voice:

“No, I am ... Something Else”.

The offscreen, high-pitched voice replies, excitedly,

"Oh my God!"

The clip showcases Mooswa's linguistic flexibility and humor, echoing the anti-colonial comedy of Indigenous social media creators like the 1491s (Berglund, 2016; Goeman, 2011) and Indigenous parodies of white people (Basso, 1979). Above, Mooswa jokes in a relaxed, unmarked conversation, disrupting stereotypes of Indigenous North Americans as stoic, and settler assumptions of Indigenous North Americans as existing in the past (Berglund, 2016). He then performs a second speaker, using "mock white girl" voice (Slobe, 2018), higher pitch, and excessive politeness (Carris, 2011) to parody the racial microaggression of a white woman accosting him, and asking him about his "Native American"-ness. Clearing his throat to show himself shifting into performance mode, Mooswa dons the gaze and stance of a stereotypical, "mystical Indian" persona. He replies, using ponderous delivery and exaggerated mid-phrase pausing of "Hollywood Injun English"—a media-produced, imagined speech variety that indexes racialized assumptions about Indigenous North Americans (Meek, 2006, 2020). Back to offscreen mock white girl voice, Mooswa exclaims "Oh my God!" with exaggerated, hi-lo Valley girl intonation and phrasing (Slobe, 2018). Through dexterous style-shifting, Mooswa critiques Indigenous stereotypes and related settler colonial assumptions, as well as Indigenous performances of stereotypical indigeneity for others (Berglund, 2016). He also parodies a "hyperwhite" gendered and classed style associated with stereotypically "empty-headed," privileged white women (Eckert, 2008; Slobe, 2018) to critique whiteness and non-Indigenous surprise at encountering Indigenous Peoples and ways that Indigenous North Americans are racially "othered" in everyday interactions.

Like many Something Else jokes, Mooswa's clip further shows how commonplace interactions and struggles over Indigenous self-definition become even more absurd and dehumanizing when "Something Else" replaces terms like "Native American" and "Indigenous" that already obscure Indigenous North Americans' unique, diverse, and multiple identities. Using wide-ranging remixes of images, edited lines, and media references, Indigenous creators quickly, playfully, and pointedly connected Something Else to symbolic violence in old Westerns and children's movies, racial regulation in documents tracking blood quantum and tribal citizenship, DNA test-related challenges to Indigenous Peoples' ways of determining community membership, and colonization itself. Among other moves, they also remixed Something Else with ironic lines about indigeneity from Indigenous-produced media, as the fresh, multi-platformed, multimodal collective burst of expression rejected Something Else as more of the same old settler colonial identity politics.

Amid widespread election anxiety, creators also shared love and admiration for Indigenous strength in humor with posts like, "The world is all stressed out and Natives are just laughing all day about being labeled Something Else by CNN. I love us." As Sherry McKay, an Ojibway Anishinabe influencer from Sagkeeng First Nation concluded, in her own curated mix of Something Else posts, "That's just one of the 1000 reasons why I love being Indigenous, because we're resilient."

Natives React host Willie reflected,

It's becoming a situation where all of us Indigenous People are taking away the power of this Something Else, of being the Other. Like, "OK, sure," in a sarcastic manner. And it is pretty neat that we're not letting that define us, we're making fun of it, this is how we do Something Else is now being replaced with something deadly, talking about changing the narrative.

Patrickisnavajo (2020b).

Comments underscored the familiar, collective power of Indigenous content creators' spontaneous, critical humor. Remixing Something Else into "something deadly"—dangerously subversive and excellent—Indigenous social media creators helped a media movement "change the narrative," with inventive commentary, Indigenous connection, and community.

Playing the way he felt it: Doggface208 "vibes indigenously"

The digital universe provides growing modalities in which individuals create and express ideas and experience, drawing upon Indigenous strategies of remembering, reframing, intervening, representing, and connecting (Berglund, 2016; Smith, 2012) and Indigenous inventiveness through languaging. The viral TikTok from 2020 described below takes Blommaert's "language-in-motion" (2010, p. 5) figuratively and literally, through an interplay of linguistic and physical representations. TikTok is described as a place of "creativity and experimentation" (Anderson, 2020, p. 9) where users "play without adhering to visual styles and narratives" (Bresnick, 2019, p. 10). As part of the long tradition of Indigenous expressions of affirmation and community building, Indigenous TikTok creators are playing in the new environment, offering robust shows of creativity (In Focus, 2021).

One illustrative example is the viral TikTok "Morning Vibe" by Nathan Apodaca, also known by his TikTok handle, Doggface208. Posted on September 25, 2020, the evocative video shows Apodaca casually maneuvering his longboard on a major thruway, while singing along to the Fleetwood Mac song, "Dreams," drinking from a gallon-sized container of Ocean Spray Cran-Raspberry juice, all while, with seeming effortlessness, filming himself with his cell phone. Apodaca's video deeply touched something. Maybe the *duende*? In Lorca's words he seems to embody "the blush of all that is truly alive" (Gilmore, 2016, p. 55).

The TikTok embodies Apodaca's casual coolness, jamming out as he skateboards along the highway. He begins with a direct look at the camera. His slight smile and upward nod of recognition immediately ignites connection and familiarity; his shaved head and brown skin connote a person of color and communities claimed Apodaca as a kindred relative, referring to him as "an old school Chicano." Approximately 5 seconds into the video as he navigates his board, Apodaca turns his head away from the camera, exposing a large two feather tattoo behind his right ear stretching down to his neck, suggesting his Indigeneity. Indigenous Peoples claimed him in numerous posts, referring to his "deadly uncle vibes," (the honorific "uncle" is common in many Indigenous communities) as well as calling him "cousin" and "elder." In subsequent interviews, Apodaca identified himself as Northern Arapaho and Mexican.

The duende-filled "vibe" that so many connected to in the video weaves a deep tapestry. It is Indigenous survivance as an immediate action within a historic context. Apodaca evokes desire to survive, to be freshly alive, to move beyond the death, destruction and despair of recent years. One commenter noted that Apodaca's TikTok was "The One Positive Thing in 2020." The clip connects to a long history of resistance to settler colonial tactics. His skateboarding is part of a history of Native American skateboarding culture. His singing of "Dreams," evokes survivance and thrivance by centering Indigenous ways of being in the world. Apodaca's old truck, with 300 thousand miles on it, had broken down on his way to work. Undeterred, he grabbed his longboard and his juice and continued riding on to his destination. The challenges that morning make his "vibe" all the more a celebrated example of thrivance.

The 84 million views of Apodaca's clip is only one indicator of the video's impact. Many news stories explored the phenomenon of the video. The videos have been liked and commented on thousands of times, as well as inspiring multiple memes and copy videos, including one by a Fleetwood Mac band member. Many commenters describe the "vibe" of the video, noting its "Chill," "At Peace," and bringing "the world together" esthetic. Apodaca's "vibe" resonated powerfully with many in Indigenous communities.

The Natives React channel dedicated an episode (Patrickisnavajo, 2020a) to celebrate Apodaca, opening with the hosts drinking from the now iconic gallon sized Ocean Spray Cran-Raspberry juice bottles and "vibing Indigenously." The hosts share a humorous and moving video montage of the different ways Indigenous Peoples reinvented the video—lip syncing to Dreams while horseback riding, ice skating, and riding bikes. "I think it is so awesome to see the Native Community come together ... it warms my heart" (Patrickisnavajo, 2020a).

With so many Native communities connecting to this "Rez Anthem," the lyrics themselves offer a poetic lens of *duende* to consider,

Now, here you go again

You say, you want your freedom

Well, who am I to keep you down

It's only right that you should

Play the way you feel it

Nicks (1977).

Willie notes the video is a "reminder to enjoy life, to not take it so seriously (Patrickisnavajo, 2020a)." As he calls out to "play the way you feel it" maybe Apodaca is encouraging Indigenous Peoples to be who they are in the ways they decide; to assert their own Indigenous identity, authenticity and sovereignty. Apodaca's embodiment of Indigeneity offers an opportunity to explore representation, as social media practices of Indigenous Peoples illustrate displays of culture.

Outside observers may create or reify artificial signs of authenticity and identity of Indigenous Peoples, imposing biased views, relying on master narratives (Takaki, 2012) and single stories that restrict Indigenous expressions of being. Concepts of authenticity are "embedded ... within several colonialist systems ... held hostage by fossilized romantic notions of cultural purity and essentialist origins" (Urrieta, 2017, p. 256). Other than the feathers in Apodaca's tattoo, there is little in the video which would strike community outsiders as "authentic" Indigenous cultural practice. Nevertheless, Apodaca was almost immediately recognized and claimed by Indigenous Peoples. Apodaca's liberating authenticity is deeply felt by all audiences as they glide with him—immersed in his five senses—playing the way he feels it.

Indigenous content creators assert Indigenous “presence over absence, deracination, and oblivion,” (Vizenor, 2008, p. 1), and use humor to “laugh at”—and love—“themselves, laugh at others and hold all aspects of life together without letting anybody drive them to extremes” (Deloria, 1969, p. 53), renouncing “the unbearable sentiments of tragedy, and the legacy of victimry” (Vizenor, 2008, p. 1). Their offerings feed creative glory and Indigenous life force into the world.

Conclusion

The quest for creative expressive forms, inspiration and *duende* is a driving force in all the arts and evokes a deep basic human yearning for passion, love, joy, meaning, escape and freedom from the challenges of life. While the *duende* might be manifest in a wide variety of meaningful ways in Indigenous life, in this essay we have chosen to highlight some of the particular ways Indigenous Peoples and communities draw on the *duende* to struggle creatively with the profound and lasting wound of colonial oppression. In each of these three stories, the spirit of *duende* is evoked in Indigenous contexts by *the wound that never heals*. In each case the newly generated, “freshly created” social communicative practices bring radical change in forms of affirmation, healing and transcendent resilience to resist the enduring pain and trauma of settler colonial oppression.

Almost 50 years ago two young children playfully and lovingly invented a liberating language that defiantly transformed a rigid racialized colonial space in a remote Indigenous Kenya hillside community. The traditional cultural practices of Hawaiian mele and hula were poignantly, powerfully and politically (re)created and innovatively transformed with healing grace and evocative spirit as Kānaka Hawai‘i, Indigenous Peoples, communities, and nations stood in solidarity with *kia‘i* on the mauna. Indigenous social media content creators engaged in widespread transidiomatic practices of resistant healing humor, irony, survivance and thriving with the reversal of a narrative of erasure in the global #Something Else phenomenon and the hypnotic mesmerizing “cool vibe” of Apodaca’s viral video. Each example highlights the powerful struggles and effective agency of *just languaging* with *duende* as healing communicative practices in the face of settler colonial oppression. The poignance, passion, pain and pleasures of the *duende* are powerfully manifest through social semiotic communicative inventive practices in a battle for survival, pride, joy and community renewal. The heightened state of emotion, expression and heart in these examples inspires human resilience, healing creativity, liberating freedom and innovative *just languaging* in the *duende’s* spirit of evocation.

Introduction

San Juan, Puerto Rico - Verano de 2019

Puerto Ricans engaged in a 3-week protest to oust then-governor Ricardo A. Roselló. Protesters gathered in front of La Fortaleza, the governor’s residence, and, in one of the more memorable acts of resistance, read “bedtime stories” to the Puerto Rican Constitution. This literal and symbolic act emerged as a challenge to the assaults Puerto Rico’s Police combat squad, la Fuerza de Choque, had consistently committed around 11 p.m. each night, claiming protestors’ constitutional rights expired after 11 p.m. because “La Constitución Duerme/the Constitution sleeps.” Feminist organizations and children’s authors read aloud the U.S. Constitution and children’s books to the Puerto Rican Constitution (1952) as bedtime stories. After three weeks of protests across the island, Roselló announced his resignation.

Paraphrased from [García \(2021\)](#).

We start this piece with a snapshot of *prefigurative hybrid literacies* in action. In the example above, Puerto Rican citizens took to the streets and used the United States constitution and Puerto Rican children’s literature to enact critiques of callous, abusive policies and practices by the Puerto Rican (pro-U.S. statehood) government. Although the reading of bedtime stories stemmed as a response to la Fuerza de Choque’s violent assaults, the acts also speak directly to the multiple violent, oppressive practices the governor and other high-level government officials engaged in as Puerto Ricans on the archipelago struggled with an ongoing economic crisis and the aftermath of Hurricanes Irma and Maria. Hundreds of leaked messages between Roselló and government officials showed the illicit use of public resources and funds for partisan purposes, misuse of public funds and time for non-government work, and misogynist, classist, disparaging remarks against the Puerto Rican community. By bringing in literacy practices considered as belonging in the private sphere to a public space, participants engaged in hybrid literacy practices to challenge oppressive, dehumanizing practices by those in power. Bedtime stories and protests, practices typically regarded as belonging to separate social contexts, are thus taken up together to generate new discourses—a third space—and *prefigure* the equitable, just society Puerto Ricans wish and deserve to live in.

The following chapter provides three examples of prefigurative hybrid literacies mobilized by transnational, subaltern communities in Puerto Rico, Mexico, and the Mindanao region of the Philippines, respectively. Despite their disparate geographical locations, these three contexts share histories of imperialism and colonization, their communities experiencing ontological precarity through constant exposure to economic insecurity, injury, violence, and forced migration ([Butler, 2004](#)). This piece will illustrate how these communities’ engagement with prefigurative hybrid practices allows disenfranchised, nondominant ([Gutiérrez, 2008](#); [Gutiérrez et al., 2009](#)) people to create third spaces ([Gutiérrez, 2008](#)) by drawing from multiply-situated knowledges. Such an

approach nurtures decolonial imaginaries (Pérez, 1999; Torres and Medina, 2021) “resulting in geographical and ideological repositioning” (Schechter, 2012, p. 2) that delinks these communities and lands from the dominant colonial US imaginary.

Prefigurative hybrid literacies

In this piece, we use the term *literacies* to capture local, multiple, and changing competencies and practices of language usage in the service of interacting with and manipulating texts, which shape and are shaped by sociocultural practices, contexts, mediums of representations, and users’ identities (Jocson, 2005/2006). Moreover, Jocson (2005/2006) defines *hybridity* as “the convergence and (re)emergence of cultural practices that create or lead to alternative possibilities in individual or social but goal-oriented activities such as learning and production” (p. 51). We also wish to highlight the term’s “community-based yet experimental, radical, but not static or dogmatic” nature (Gomez-Peña, 1996, p. 12). By using the term *hybridity*, we hope to capture how “we are not the product of just one culture; that we have multiple and transnational identities; that we contain a multiplicity of voices and selves, some of which may even be contradictory” (Gomez-Peña, 1996, p. 12).

Birr Moje (2013) describes hybrid literacies as intersecting knowledges, expressions, and ways to make meaning:

Various scholars have taken up the ideas from hybridity theory and applied them to the idea that the literate practices valued in home, community, peer groups, and schools can come together in unpredictable ways to produce new literate practices or conventional practices (both everyday and academic) used for unconventional purposes.

Birr Moje (2013, p. 361).

This idea of two practices coming together to create a new practice (as opposed to merely a combination of the two) is what links hybridity to third space (Gutiérrez, 2004). Third spaces center “in-betweenness” and the intersection of differing practices, identities and possibilities to create something new (Birr Moje, 2013). As with the opening example, hybridity involves “the integration of competing knowledges and discourses” (Birr Moje, 2013, p. 361); in a third space, “what seem to be oppositional categories can actually work together to generate new knowledge, new Discourses, and new forms of literacy” (Birr Moje, 2013, p. 362). These new discourses, forms of knowledge and literacies stem from tensions and ruptures (Jocson, 2005/2006).

Finally, we use the term *prefiguration*, which has links to decolonial resistance. Walia (2013) in particular notes:

Decolonization is a framework that offers a positive and concrete prefigurative vision. Prefiguration is the notion that our organizing reflects the society we wish to live in—that the methods we practice, institutions we create, and relationships we facilitate within our movements and communities align with our ideals.

Decolonizing Movement Borders section, para. 3.

Moreover, Walia (2013) argues that “decolonization movements create an alternative to power through committed struggle against settler colonialism, border imperialism, capitalism, and oppression, as well as through concrete practices that center other ways of laboring, thinking, loving, stewarding, and living” (Decolonizing Movement Borders section, para. 5).

When we refer to *prefigurative hybrid literacies*, then, we mean integrated, oftentimes competing knowledges and discourses that generate new knowledges/discourses in the service of decolonial resistance, thus working to dismantle oppressive, racist systems that fail to align with subaltern communities’ ideals and hopeful futures. Through this decolonial resistance, subaltern communities work toward “disrupt[ing] the dominant ordering schemas of modern society, specially the binaries of colonizer/subaltern and citizen/alien, identity pairings that usually map on to a white/black (or white/nonwhite) racialized social imaginary in the United States” (Schechter, 2012, p. 4). The literacies we describe in this chapter are a form of prefigurative pedagogy as well (Campano, 2013); they were staged not only to educate a broader audience about societal injustices, but also to collectively embody alternative decolonial forms of sociality premised on interdependence in the midst of oppression.

Transnationalism, precarity, and decolonial resistance

Transnationalism captures social, economic, and political attachments individuals maintain in both their home nation-state and the nation-state(s) to which they have moved. Linkages between two or more different countries occur through remittances, marriages, media consumption, communications, and travel, to name a few (Foner, 1997; Morawska, 1999; Portes et al., 1999). Transnationalism is a concept closely linked to identity, since (a) the attachments (im)migrants maintain in multiple nation-states are often the result of (perceived) commonalities in terms of language, customs, and cultures in multiple sites, and; (b) individuals and communities must negotiate their identities across different contexts (Vertovec, 2001). Çağlar (2001) points out (im)migrants “weave their collective identities out of multiple affiliations and positionings and link their cross-cutting belongingness with complex attachments and multiple allegiances to issues, peoples, places, and traditions beyond the boundaries of their resident nation-states” (p. 610).

However, despite the constant flow of goods, ideas, and communication made possible by technological advancements, political borders have influenced the physical (im)mobility of nondominant, racialized subjects. [Walia's \(2021\)](#) work examines how empire, capitalism, and human-made disasters simultaneously displace vulnerable, oppressed populations as they limit their mobility through colonial policies and technologies that serve neoliberalism tenets. Moreover, empire and capitalism actively construct marginalization and oppression, unequally ascribing value to and protecting certain bodies over others ([Kasmir, 2018](#)).

This piece will highlight the potential of prefigurative hybrid literacies as both sites of (de)colonial ([Mignolo, 1995](#)) resistance and mediums to nurture decolonial imaginaries ([Campano et al., 2020](#); [Pérez, 1999](#)). We will focus on examples across three different contexts—Puerto Rico, Mexico, and the Mindanao region of the Philippines—with shared histories of imperialism and colonial oppression, illustrating how nondominant communities engage in prefigurative hybrid literacies to (a) equitably redistribute access to information transnationally and (b) encourage transnational allyship toward liberatory, humanizing ends ([Luke, 2012](#)).

Puerto Rico

Imperialism and resistance in “La Isla del Encanto”

Puerto Rico became a US colony in 1898, when the United States followed an expansionist agenda that included the acquisition of Spanish ultramarine territories after the Spanish-American War. Race became an organizing principle for the US nation-state during this period of capitalist global expansion ([Singh, 2004](#)), and Puerto Rico is a prime example of this dynamic, relegated to a liminal space between inclusion and exclusion. As [Burnett and Marshall \(2001\)](#) document, “the Insular Cases, decided between 1901 and 1922, invented and developed the idea of unincorporated territorial status in order to enable the United States to acquire and govern its new ‘possessions’ [Puerto Rico, Guam, and the Philippines] without promising them either statehood or independence” (p. 2).

As an unincorporated territory, the island has been the subject of more than 100 bills introduced in the US Congress that attempt to (re)establish the island’s connection to the US in terms of citizenship, nationality, and naturalization, resulting in what [Venator-Santiago \(2017\)](#) terms “inclusionary exclusion” (p. 38). Puerto Ricans became US nationals through the 1917 Jones Act and obtained limited autonomy as a commonwealth in 1952 ([Duany, 2002](#)). However, the US created a system with provisions to limit the island’s agency and economic growth ([Burnett and Marshall, 2001](#), p. 10). As members of a commonwealth, Puerto Ricans can elect a governor and local public officials, but they are unable to vote in presidential elections and have no autonomy over “currency, defense, external relations, communications, the postal service, social security, and interstate commerce” ([Godreau and Bonilla, 2021](#), p. 511). The professed intention of protecting and bringing civilization to Puerto Ricans served to give the US nation-state the high moral ground as it actively worked to exploit the land and its residents, maintaining the island’s unequal, vulnerable status in the US polity.

[Duany \(2002\)](#) argues Puerto Rico is a “postcolonial colony” that, despite US intervention, has a strong national identity (i.e., cultural nationalism). Moreover, Puerto Ricans occupy a unique position in the US polity. According to [Duany \(2002\)](#), “Puerto Rico’s migratory patterns are distinctive for: (a) the island’s “persistent colonial condition,” (b) “the sheer magnitude” of its diaspora, and (c) the circular and return patterns of migration in which Puerto Ricans have engaged since the 1940s” (p. 13).

[Lloréns’ \(2018a\)](#) argues that “in Puerto Rico, societal vulnerabilities result from a long history of colonial subjugation, economic hardship, environmental injustice, infrastructural neglect, and, at the local island level, a broken rule of law” (p. 156). She identifies the 1980s as a critical decade when the archipelago’s vulnerability increased dramatically. Social problems such as crime, poverty, and unemployment as well as greater socio-economic disparity increased, and the trend of privatization began ([Lloréns, 2018a](#)). Unfortunately, the socio-economic problems resulting from the archipelago’s colonial status were only exacerbated after the land-fall of Hurricanes Irma and María in 2017, a series of earthquakes in 2020, and the global pandemic still in effect at the time of this writing. As [Lloréns \(2018b\)](#) concludes, Puerto Rico’s current economic crisis is compounded by “the social forces of five centuries of colonization by Spain and then the United States, which largely constructed the island as a site of extraction, with its people at times invisible and at others dispensable” (p. 158).

Youth literature, Puerto Rico, and the diaspora

[García \(2021\)](#) documents how youth literature and literacies have had a prominent role in Puerto Rican politics and activism. Puerto Rican authors on the archipelago and in the diaspora have historically used texts to nurture a strong sense of cultural nationalism and make sense of Puerto Rico and Puerto Ricans’ relationship to the US. For example, [Haiman \(2014\)](#), author of *Tulipán: The Puerto Rican giraffe*, tackles what it means to be Puerto Rican, “representing migration to young readers from necessary evil to exciting inevitability to, finally, an asset for creative and political freedom” ([García, 2021](#), p. 206). Youth literature and literacies also often center a feminist transnationalist lens that highlights collectivity, survivance, and resiliency in the face of dehumanizing, oppressive conditions, continuing “a legacy of feminist and Afro and Indigenous pedagogies through engaging audiences in stories about self-determination and community solidarity as opposed to individual heroism” ([García, 2021](#), p. 196).

After Hurricanes Irma and María in 2017, Puerto Ricans lived without access to electricity, internet, and other communication technologies. Puerto Rican authors heavily relied on “Afro-Boricua literacy practices of storytelling theaters and cultivating community critical literacies, understanding that government institutions often fail to support communities of color” ([García, 2021](#), p. 28).

Torres and Medina (2021) examined 4 children's books published after Hurricanes Irma and Maria: *Mi Isla Bella/Mi Isla Hermosa* (Pastrana-Andino, 2018), *Por Ahí Viene el Huracán* (Rexach-Olivencia, 2018), *La Cucarachita Martina y el Huracán* (Marichal-Lugo, 2019), and *Thiago y la Aventura del Huracán* (Arroyo-Pizarro, 2018). They concluded these children's books illustrate communal and activist practices toward epistemic justice and foreground "decolonial ruptures that reclaim local knowledges," thus "delinking the island from a dominant colonial US landscape and imaginary" (Torres and Medina, 2021, p. 260).

I (Astrid) engage in this work as a Puerto Rican who was born and raised on the island but had no exposure to texts such as these as a child. As an adult, I finally felt what it was like to have characters in stories share my cultural and linguistic background. More importantly, I was exposed to characters and stories that centered power, strength, and resistance, and I wonder about the effect texts such as these would have had on me at a younger age. I also engage in this work as a mother who is grateful for the opportunity to share these stories and messages with my daughter. The examples in this section demonstrate Puerto Rico's rich history of prefigurative hybrid literacies, where discourses centering decolonial resistance intersect with the genre of children's literature, creating and sustaining stories and culturally and linguistically diverse practices that draw from multiply-situated knowledges and disrupt the dominant colonial US imaginary.

La Borinqueña: celebrating and nurturing transnational Identities

Edgardo Miranda-Rodríguez's comic series, *La Borinqueña*, was created in 2016 and features Marisol Rios de la Cruz, an Afro-Boricua student from Brooklyn who goes to live with her grandparents in San Juan, Puerto Rico to complete her graduate studies as an environmental studies major. While in Puerto Rico, Marisol sets in motion a series of events that lead to Taíno goddess Atabex granting her superpowers, including the ability to control storms and create portals that allow her to travel freely across borders.

Miranda-Rodríguez's work centers a diasporic intersectionality that "not only acknowledges but actually privileges the Puerto Rican migrant experience" (García, 2018, p. 72). Castillo points out how, in *La Borinqueña's* case, "the soul and spirit of the island of Puerto Rico flows through Marisol's veins *because* [emphasis added] of her upbringing away from the island as well as her return to it to seek out her roots" (Castillo, 2021, pp. 1023–1024). This positioning encourages transnational allyship between Puerto Ricans on the island and the diaspora in particular. Moreover, Marisol provides a counter-narrative Puerto Rican hero, since the protagonist deviates from the typical White, middle-class male perspective, instead foregrounding Marisol's intersectionality as an Afro-Boricua woman from a working-class, bilingual background (García, 2018). Marisol's costume gives the illusion that the character is draped in the Puerto Rican flag, she translanguages—using the named languages of English and Spanish to navigate the world—and she maintains ties in both New York and Puerto Rico. In this way, the character embodies "a diasporic Puertoricanness [that] serves as an anticolonial tool to subvert stereotypical, disempowering national myths about races, gender, and class" (Castillo, 2021, p. 1023). In short, the text *prefigures* the character's in betweenness as a source of strength to be valued and nurtured. In addition, it represents a "decolonial, anti-patriarchal turn in the Puerto Rican imagination" (García, 2021, p. 203).

Marisol's backstory and the acquisition of her powers is firmly situated in multiply-situated knowledges spanning space and time, making it a prime example of hybrid literacies in action:

Atabex shows Marisol the Taíno resistance to Spanish domination; the moment pro-independence activist Mariana Bracetti sewed the flag of Lares, the first symbol of Puerto Rican anti-colonial resistance in the 1868 rebellion against Spain; Puerto Rican soldiers fighting in the U.S. Army unfurling the Puerto Rican flag while in a trench; Nationalist Party leader Pedro Albizu Campos, convalescing from skin burns that one scholar has found were caused by covert radiation in the 1950s; and the Young Lords marching through the streets of New York City in the 1970s.

García (2018, p. 79).

This example of prefigurative hybrid literacies draws from various histories and knowledges to delink the island's history from the US imaginary and *prefigure* a community of resistance fighting for liberation (García, 2018).

Finally, another important component in Marisol's story is the sense of hope and possibility at the center. García (2021) argues Miranda-Rodríguez's work allows readers "reimagining and restoring the present" (p. 74) to engage in collective dreamwork (p. 71) or *prefiguration* involving Puerto Ricans on the island and diaspora. *La Borinqueña* is rife with references to anti-colonial Puerto Rican culture, including excerpts from poetry written by Julia de Burgos, a Puerto Rican poet and activist for women and Afro-Caribbean writers; lyrics from the revolutionary national anthem; and a costume featuring the light blue color used in the original Puerto Rican flag, later changed to navy to better resemble the US flag and gain favor with the federal authorities (García, 2018). As García (2018) argues, "by including diverse literary allusions and locations as important cultural signposts of Puerto Ricanness, Miranda-Rodríguez suggests that racial mixture, anti-colonial resistance, and cross-locational mobility and adaptability are part and parcel of the Puerto Rican experience" (p. 79).

Mexico

Historical roots of Ralámuli's present context

Each part of Mexico has a specific history of the Original Peoples' re-existence (Walsh and Mignolo, 2018) in the face of and in resistance to domination by the military and religious conquerors of the Spanish Empire and, later, by the Mestize Mexicans,

who arguably constitute the official Mexican nationality. In some parts, this resistance has had notes of coexistence and cultural syncretism, as in the case of the Nahua Peoples in the center of the country during colonial times (Escalante Gonzalbo, 2020). In other latitudes of Mexico, the Original Peoples, such as the Yaqui People in the current state of Sonora, have faced the government's attempts of extermination and genocide (Turner, 1969). And in other corners, the Original Peoples have managed to counteract domination from colonial times to the current 20th century through the isolation provided by Mother Nature, as in the case of the Ralámuli in our contemporary Chihuahua state. This section will focus on the Ralámuli nation's fight, spanning at least 70 years, and the ways in which they use their literacies to resist the dispossession of their lands. To this end, it is necessary to give a brief historical contextualization of the theory of racial formation in Mexico and of the relations between the various nations that make up Mexico (i.e., the relations of the Original Peoples with the Mestizes). This will help us better understand the great feat of the Ralámuli people in their struggle to survive in the lands they have inhabited for millennia.

Before the European colonizers arrived to Abya Yala in 1492, the Original Peoples had been established for more than 35,000 years (Escalante Gonzalbo, 2020) in what we now call Mexico. Beyond the linear temporality of modernity/coloniality (Mignolo and Walsh, 2018), these tribes had developed unique civilizations in harmony with Mother Earth, in regions formerly known as Oasisamerica, Aridoamerica and Mesoamerica. However, the arrival of the Spanish Crown and the Catholic Church conquerors to Abya Yala permanently disturbed the being and knowing of Original Peoples across the continent. Between 1521 and 1821, the political demarcation we now call Mexico was a colony of the Spanish Empire called New Spain. Its highly diverse population was constituted by Native Americans who were dispossessed of their ancestral land, Spaniard colonizers, and enslaved sub-Saharan Africans. Social relationships in this Colonial period were marked by a caste and racial system that allowed, under the auspices of the Spanish Crown and the Catholic Church, the admixing of cultures and bodies of Native, European and African peoples. By 1810, the New Spain's population was 39.5% mixed (Lagunas, 2018).

The mixed population was regulated by the Crown under an intricate hierarchical classification of ethno-racial categories known as the caste system, and the categories varied between 14 and 20 (Palacios, 2012, pp. 38–39). In this system of corporal regulation, the Mestizes were the offspring of a Spaniard male and an Indigenous woman and constituted the third most powerful ethnic group during the Colony, behind the Spanish and the Criollos. Under this racial formation theory, "the meanings of 'Spanishness,' 'Indianness,' [sic] and 'mestizeness' [sic] were formulated from a specific historical context and within a complex web of power relations where social identity and status were constantly negotiated" (Palacios, 2012, p. 28). Accordingly, the notion of Indigenous people was constructed as an amalgamation of various identities and tribes, and as a common group in need of Christian salvation. The ethno-racial category of Black people derived from the dominant ideology associating dark skin with both the biblical story of Noah's curse of Ham and Aristotle's view of this group of people as natural slaves (Palacios, 2012, p. 34). Within each racial category, additional caste distinctions and exceptions determined peoples' rights and obligations (Palacios, 2012).

After 300 years of this colonial period, the new country of Mexico continued to use systemic racism to shape its identity as a nation-state in the 19th and 20th Centuries (Palacios, 2012). Following the Independence from Spain, Mexican Mestizes were in a privileged position that allowed them, in time, to take political and cultural control of the newborn country and to create the official national identity under the thesis of mestizefilia. Rooted in legacies of coloniality, systemic racism and biological determinism that uphold Eurocentric epistemologies, mestizefilia created a cultural homogeneity as the standard of what it means to be Mexican (Palacios, 2012), negating the diversity of cultures, cosmovisions, languages, and skin colors that actually inform Mexico. Mestizefilia was also used by the founding fathers of Mexico to eliminate the cultural presence of contemporary Indigenous cultures, relegating them to Mexico's past (Palacios, 2012) and "defin[ing] the indigenous [sic] as 'problems' in need of paternalistic intervention" (Palacios, 2012, p. 71).

The Ralámuli Nation's literacies for resistance

I (Ericka) engage with the Ralámuli nation's literacies as a Mexican Mestiza born and raised in the Northern land we now call Chihuahua, that once belonged to the Original Peoples referred to as Conchos. I have been a witness to the pride and resistance the Ralámuli people have as they face the power imbalance in their relationship to Mestizes, and I'm choosing to use the privilege I have through academia to denounce systemic racism in Mexico and to honor and aid the Ralámuli nation in their fight for their ancestral lands.

In line with theories of civic nationhood (Santos, 2013), the article number two of Mexico's Political Constitution states the Mexican nation is unique, indivisible, and with a pluricultural composition. However, Indigenous peoples across Abya Yala demand that, along with civic nationhood, states should also recognize ethnic-cultural nationhoods, i.e., a kind of nationhood founded on a collective sense of belonging, and sharing of the same symbolic and cultural universe (Santos, 2013). Under this premise, we can think of Mexico as a plurinational state, where Indigenous nations, like the Ralámuli's, are constantly using hybrid literacies to create coalitions with Mestize Mexicans—members of the official Mexican nation—in resisting the push of modernity/coloniality's battles against them.

These battles have social, political, economic, and historical expressions. For instance, the economy of the country has been grounded on capitalistic extractivism since the Colonial period, with disrespect toward Mother Earth. As I write this, the federal government is carrying out the ecocide of the Selva Maya in the Southern states, in favor of a highly ambitious tourism megaproject. At the North of the country, in the land of the Ralámulis, Mother Earth is being harassed through-out her forest by mining and tourism companies. In what follows, we will focus on one example illustrating how members of the Ralámuli nation are using their

prefigurative hybrid literacies to resist and re-exist (Walsh, 2020) in front of a tourism development's efforts to take their ancestral land in the town of Mogótavo.

Mogótavo is located in the Copper Canyon, in a zone highly coveted by Mestize people for tourism purposes. Diverse Mestize businesses and politicians have been attempting to displace the Ralámulis from Mogótavo since 1909. The struggle has intensified since 1980, when the Ralámulis legally requested their land. Currently, 16 members of the Ralámuli nation, including 3 autochthonous authorities, are facing legal prosecution by politicians with property titles who wish to dispossess the community of their lands.

In the multiple rallies they organize in highways and cities, the Ralámuli people of Mogótavo use their hybrid literacies to oppose their land dispossession. The ancestral dances, songs, and music that have been practiced during millennia to honor Mother Earth in the more private spheres of home and community are now being displayed in a more public sphere. By bringing these literacies to a Mestize audience, the Ralámuli people critique and resist oppressive, dehumanizing, imperial practices and systems that wish to eradicate their histories, multiply-situated knowledges, and their very being. As in our opening vignette, ancestral dance/music and protest are brought together and generate a third space that *prefigures* the equitable, just society the Ralámulis wish and deserve to live in. Moreover, they use their literacies to create a kind of transnational coalition with Mestize people, members of the official Mexican nation, as they advocate for themselves. Beyond the presence of Mestize activists and lawyers in these manifestations and in the courtroom, this coalition building is particularly visible in an object Ralámulis have incorporated from Mestize literacies into their rallies: the banner. These objects, material agents of Ralámulis' hybrid literacies, are written in hispanicized Ralámuli language over small pieces of cardboard, or in Spanish on plastic, printed banners.

The case of the resistance and re-existence of the Ralámuli nation through their hybrid literacies can be read as a counterstory to mestizofilia. Moreover, these practices nurture decolonial imaginaries that reposition and delink community and land from the dominant colonial US imaginary. As mestizofilia depicts Indigenous peoples in Mexico as an obstacle to progress, the Ralámuli nation has learned from the literacies of the Mestizes to defend their land and their cosmovision from intruders. The strength and honor of this nation, as well as their struggles against systemic racism, have echos everywhere in the modern world, and join the small hopes (Walsh, 2020) of colonized, subaltern subjects that together crack the matrix of modernity/coloniality.

The Philippines

Context of imperialism and resistance

The Philippines, although on the other side of the globe, shares a colonial history with Puerto Rico and Mexico. Composed of more than 7000 islands and a multitude of ethnolinguistic communities, the Spanish delineated its political borders in the mid-1500s. "Las Islas Filipinas," named after King Philip II, remained a part of Spain for roughly three centuries. The ideological justification for colonization was primarily religious: to "save the souls" of the native inhabitants, who were deemed inferior. The violent imposition of Christianity worked in tandem with economic plundering through land ownership and labor exploitation. It is important to note that, prior to colonization, and for many indigenous people in the Philippines to this day, land is part of a collective commons, a source of food and communal well-being. As a result, the Philippines has a long history of native resistance to colonial occupation symbolized by iconic figures of the Spanish colonial period, including Lapu Lapu, Gabriela Silang, Jose Rizal, the Katipunan, and Emilia Aguinaldo.

In 1898, the United States "acquired" the Philippines, along with other territories such as Puerto Rico, Guam, and Samoa, from Spain after the Spanish American War (Immerwahr, 2019). The Filipinos resisted their new colonizers and, by some estimates, roughly one million Filipinos were killed during the Philippines-American War (1899–1902). While brutalizing Filipino insurgents through a scorched-earth campaign, American imperialists simultaneously employed education and literacy as a soft tool of hegemony to civilize "America's Little Brown Brothers" through "benevolent assimilation." Around 1903, roughly 500 Thomasite Educators from the United States arrived in the Philippines to establish a public education system in English. One such educator, Carter G. Woodson, drew on his experiences in the Philippines to theorize the miseducation of Black students on the continental United States, who also did not have a curriculum that connected to their history and culture (Woodson, 1933/1999). The colonial project has thus employed not only conquest and genocide but epistemicide—the destruction of indigenous knowledge systems—and the stratification of humanity into those who are human and those who are positioned as sub-human and perpetually behind in the journey toward modernity (Santos, 2014).

Although the Philippines became an independent nation in 1946, many argue that it remains to this day subject to neocolonial economic dominance by Western Countries and multinational corporations. To complicate matters even further, many communities in the Philippines, including the Lumad (an umbrella term for the indigenous people of the southern island of Mindanao) and the Moro (Muslim) may be considered inhabitants of a settler colonial society. In this case, the settlers include Filipinos from the North, as well as an autocratic State that seizes indigenous lands for corporate mining and logging. The Lumad and Moro are displaced and terrorized through practices such as "red tagging" (unjustly accusing civilians of being communist to justify persecution and murder) and the harassment of Lumad schools for striving to preserve indigenous knowledge and value systems that are tied to the land.

“We call her Ina Bai”: mobilizing young adult fiction and storytelling

Just as literacy can be a weapon of oppression, it can also be a tool for anti-colonial liberation. Jose Rizal, for example, wrote novels that helped Filipinos imagine a world free of Spanish domination (Campano and Ghiso, 2011). In contemporary times these literary legacies continue. For example, *We Call Her Ina Bai: How Strong Women Are Made* (Santiago and Valle, 2021) is a poignant and gripping narrative of the struggle and resilience of the indigenous Lumad people of the Mindanao region of the Philippines. Fighting to protect their ancestral land and way of life from the plunder of multinational corporations, government soldiers, and local paramilitary squads, the Manobo community of the Pantaron Mountain Range have endured settler colonial displacement, state sanctioned terror, and inadequate access to health care and education. In this fraught context, leaders from the community have nonetheless risen to build solidarity within and beyond the Lumad people in order to resist their oppression. *We Call Her Ina Bai* tells the story of two of these powerful leaders, Sharmaine and her grandmother, Bai Bibyaon Ligkayan Bigkay, or Ina Bai, and is itself an outgrowth of this solidarity and collective effort.

Written in lucid and often poetic prose, the book is in the spirit of indigenous testimonials such as *I, Rigoberta Menchú* (Menchú and Burgos-Debray, 1992), which focuses on the Mayan people of Guatemala. The testimonial genre tells communal history through the voices and histories of individuals, and in doing so provides a counter-story to “official” accounts and erasures perpetuated by government propaganda. *We Call Her Ina Bai* is a text that illustrates hybrid literacies at play, since it weaves back and forth in both time and perspective between Ina Bai and Sharmaine. In doing so, the text artfully captures both the power of intergenerational, ancestral knowledge and the importance of adapting to new times and growing together as a community.

I (Gerald) read *We Call Her Ina Bai* from my position as an education scholar at a university in the Global North. I have never been to the Philippines, but I have ancestral roots in Mindanao from my grandfather, who migrated to the United States as a colonial subject at the beginning of the 20th Century during the American imperial occupation of the archipelago. I never imagined that a part of the history of Mindanao and its people would ever become accessible in a Young Adult nonfiction novella that would reach my hands here in the States. I had read about the predicament of the Lumad, but only as mediated by organizations such as Human Rights Watch, not the humanizing history as told directly from Lumad women leaders themselves, such as the women of Sabokahan.

We Call Her Ina Bai diversifies the Children’s Literature Canon because it manifests the Lumad tradition of collective storytelling in the contemporary format of YA Literature. It is a hybrid literacy practice; as the prologue states: “this story is woven in the beads and fabric of the lives of thousands of Lumad of Pantaron” (p. 10). The text confronts difficult topics, such as the horrific violence brought upon the Manobo and their right for self-defense and self-determination, head on. It is also unequivocal in regarding the role of the oppressors and their motivation: greed. Yet, it also points to another possible, more harmonious, and interdependent world—one which draws on indigenous ways of knowing and being, embodied in the tender relationship of the two protagonists.

The issues raised by *We Call Her Ina Bai* are not just relevant to one small corner of the planet; they have universal resonance. All human beings have a relationship to extractive capitalism, environmental degradation, mass displacement and migration, patriarchy, and legacies of colonialism, whether they recognize this relationship or not. All students and teachers have an obligation to grapple with what it means to teach the truth, especially when the truth is a target of dictators, strongmen, and local politicians. As such, the counter-story set forth by *We Call Her Ina Bai* serves to both redistribute the knowledges, histories, and truths circulating in this community—Lumad women leaders, youth activists, western academics, and many more—transnationally and foster a more transnational allyship toward liberatory, humanizing ends. Such an approach serves to prefigure a community of difference joined together by a desire for a more just world.

Concluding thoughts

The three examples discussed in this chapter illustrate different possibilities for disrupting hegemonic social and intellectual formations within contexts shaped by imperialism and colonial oppression. In all three examples, prefigurative hybrid literacies provide spaces to nurture decolonial imaginings and create/sustain transnational allyships toward a more just world. As Walia (2013) argues, “enacting a politics of decolonization [] necessitates an undoing of the borders between one another” (Decolonizing Movement Borders section, para. 4). In writing this piece, we hope to encourage “nurturing, emancipatory and expansive social relations and identities, forged in and through the course of struggle” (Walia, 2013, Decolonizing Movement Borders section, para. 1). It is through an understanding of the ways in which different communities create counterstories, engage in collective dreamwork, and nurture decolonial imaginaries that we can forge creative, radical, transformative solutions and partnerships toward social justice and equity.

The UN Sustainable Development Goal #4 (SDG4) calls for all children to complete a full cycle of schooling of sufficient quality to acquire the necessary skills for lifelong learning (United Nations, 2015). Yet, evidence points to pervasive deficiencies in global reading and math skills development among children and adolescents in many low-and middle-income (LMIC) countries. For instance, UNESCO (2017) estimates that over 600 million children and adolescents across the world are not acquiring basic skills in reading and math, despite several years of schooling. Other data illustrates the impact of COVID-19 on further expanding deficiencies in skills development globally. Patrinos et al. (2022) examined evidence from thirty-five international studies of documented learning loss among school-aged children during the first two years of the pandemic, with a particular focus on math and reading skills. Their analysis revealed an average loss equivalent to almost half a year of learning (Patrinos et al., 2022). Deficiencies in skills development and subsequent learning loss prompted by school closures is impacted by variations across many background characteristics. Among such variations, home (or mother-tongue) language has long been understood to play a critical role in students' ability to learn from the educational content they receive in schools (Trudell, 2016; Walter and Benson, 2012).

In this review, historical and international trends around language and policy planning are considered along with trends in the use of technology for mediating and supporting language and education with a particular emphasis on LMICs. The intersection of language choice, technology and education is one that has become increasingly pertinent as countries endeavor to enhance both access to and quality of education around the world.

Language choice and education

How languages are chosen—or “language choice”—for learning in schools, and more generally, is a multidimensional issue, ranging from the personal (such as one's feelings of identity) to the broadest (such as in national and international language policies). At the level of local societies and cultures, language preservation, especially among displaced communities and minority groups, is a current driving force behind supporting mother-tongue language use at home or in school. Such language choice for minority and disadvantaged groups often reflects a community desire for children to communicate, and eventually read and write, in their home language. For example, refugees may wish to maintain their culture and heritage through written (or spoken) language, and this can be a powerful motivator for maintaining mother-tongue literacy and education (Kelcey et al., 2022).

Concerns about the child's home language and the language of instruction (LOI) in schools in official language(s) has been a matter of academic and policy attention over many years. In numerous post-colonial low- and middle-income countries (LMICs) there may be a misalignment of home and school languages, as exemplified by the fact that both teachers and students alike may not be able to fully engage with the curriculum due to their inability to effectively communicate in the dominant or official languages (Ball et al., 2014; Cummins, 1980). As a consequence, school systems in these countries have been reconsidering their LOI policies.

While national policymakers are more intentional today about school language policies, challenges remain to effective multilingual learning in the classroom. One dimension is parent and teacher preference for dominant languages given their increasing importance to economic globalization (Benson, 2004; Wagner, 2018a). Another factor is the lack of educational resources available in mother-tongue languages due in part to low cost-benefit valuations of book publishers (Piper et al., 2016b). A further impediment to mother tongue language use is a result of LOI policies that put colonial languages into place over decades in support of Western expansionist policies. Thus, language choice can and does often include ways to ensure a community's access to expanded economic opportunities, such as by supporting the use of international or dominant language competence, but often at the expense of mother-tongue language instruction.

Another key dimension of language choice policy concerns the use of mother-tongue language (L1) in order to support dominant (L2) bilingualism in classrooms. In multilingual communities, where there is a single dominant international language (e.g., French in Senegal), the use of L1 to support learning in L2 is understood to be a sound policy choice as research indicates that children use their familiar L1 competence to learn an L2 (Benson and Kosonen, 2021). In order to better understand the dimensions of language choice, India and South Africa provide useful historical examples.

In India, language policy and language choice in schooling must take into account cultural, historical, and socio-economic variations along with changes in national educational policy. In present-day India, 96% of the mother-tongues are spoken by only 4% of the population (Narayana Singh et al., 2022). While over two centuries of colonialism strongly introduced English to the country, only an estimated 10% of the population speaks English fluently today. Colonization—both during and after—did not reduce the use of 22 official Indian languages, alongside hundreds of “tribal” and mother tongue languages (Daswani, 2001). In 1964, the Indian government decided to introduce into the school system what has come to be referred to as the “three-language formula”. This earlier policy, endorsed through the 2020 National Education Policy, requires all children to receive schooling in two Indian languages and English during their first ten years of schooling (NEP, 2020). Within this model, a learner's home language should remain the language of instruction through grade 5, but preferably through eight years of schooling where possible (Wagner et al., 2010).

In South Africa, several policies were adopted to address poverty and inequality in an attempt to reduce the impact of the country's oppressive apartheid era. The 1997 Language in Education Policy promotes home language teaching and learning in each of the 11 official languages. Similarly, the 2007 National Framework for Quality Education in Rural Areas emphasized better learning in historically under-resourced schools (SAHRC, 2012). More recently, the National Development Plan 2030 builds upon the country's current development agenda and places quality basic education as a key to achieving prosperity and equity (National Planning Commission, 2012). Preservation of local South African languages has been central to the country's post-apartheid Bill of Rights, which states that students have the right to receive education in an official language or their language of choice (Wu et al., 2021). Despite these collective policy efforts, implementing quality learning in home languages remains a persistent challenge for South African classrooms, and which disproportionately impacts poor, rural communities (Chetty et al., 2017).

Overall, language choice and educational policy depend on a multitude of factors. The overarching ecological environment that enables the use of different languages is an important driving force in determining language choice. In this context, technology becomes one of the important routes through which language choice is realized in school and society.

Technology and language choice in education planning

Information and communications technologies (ICTs) for education is increasingly viewed as a useful support for learning across the globe (World Bank, 2016). When aligned with the broader educational ecosystem, technology is particularly useful in support of learning and literacy in LMICs (Wagner, 2018a). Research suggests that when technology is leveraged to support language contexts, learning can be increased due to faster and automated analyses of learning data, and improved ways to be inclusive of those in need (Piper et al., 2016a; Castillo and Wagner, 2019).

One early ICT-based attempt of learning support for linguistic minorities in LMICs was developed for numeracy instruction in Nicaragua (Searle et al., 1976). This approach, called interactive radio instruction (IRI), was designed to deliver interactive learning to remote areas through audio broadcast with songs, dramatizations, and games (Ho and Thukral, 2009). During a scheduled time, teachers would turn on the radio and guide students through narrated pedagogical activities as a whole class. More recently, synchronous broadcast delivery has been substituted with digital audio files projected through portable speakers that give teachers the opportunity to pause and or repeat certain parts of the audio lesson as needed. Still prominent in many regions today, this approach supports quality learning by combining culturally relevant content through language and local context with interactive instruction. For instance, an early numeracy IRI project implemented in the Cordillera region of Paraguay reinforced key learning concepts in Guaraní, the indigenous language prominent across the region (Naslund-Hadley et al., 2014). Story lines and games for the Paraguay program also included references to local customs and artifacts that celebrated Guaraní heritage. Educational content delivered through interactive audio has served as an effective model for student-centered learning with technology, and has also been pedagogically supportive for teachers with limited access to ongoing training (Damani and Mitchell, 2020).

Closures of schools following the COVID-19 outbreak in 2020 resulted in a global shift toward remote learning and a greater use of ICTs in many countries (OECD, 2020). This trend produced further learning inequality stemming from a digital divide that resulted in unequal access to remote learning opportunities and resources. For instance, nearly all high-income countries provided remote learning opportunities (90%) and mainly online (Vegas, 2020). By contrast, less than twenty-five percent of low-income

countries offered remote learning (Vegas, 2020). While broadcast (either radio or television) is a more viable approach for remote learning in low-income and rural contexts (UNICEF, 2020), the digital divide created unequal access to learning opportunities for millions of students without connectivity.

Whatever the mode of delivery, there is no doubt that the use of technology has been instrumental in providing students with access to resources during the pandemic, and this will likely continue well into the future. Yet, evidence on the effectiveness of technology for education initiatives beyond mere access is mixed (Hinostroza et al., 2014). This finding is due, in part, to the fact that technology use for learning improvement has evolved into a much broader field in recent years. The breadth of design and implementation with technology has created serious debates over definitions and what can be claimed as evidence. For instance, claims relying on observational anecdotes or broad definitions of evidence without any clear indication of impact on learning gains are being replaced by empirical data about how ICTs are utilized to change learning processes and improved skills development (Wagner et al., 2014). One outcome from recent experimentation with technology and learning is clear: mere access alone will not produce consistent and positive differences. The widely cited educational technology intervention, One Laptop per Child (OLPC), underscores this outcome by producing a modest detectable impact on increased computer use and a cognitive measure of verbal fluency, but little or no impact on learning outcomes (Cristia et al., 2012). One explanation of such limited outcomes produced by OLPC is a lack of emphasis on locally relevant content. In order for initiatives to promote quality learning with technology, it is necessary to align their design and implementation with the broader language context.

A framework for language, technology, and education

One useful framework for examining the interaction between language, technology, and education derives from the ICT for education (ICT4E) framework proposed by Wagner et al. (2014). The framework originally comprised four distinct but overlapping components: intervention purposes, intended end users, devices, and context. When this framework is applied, a design solution for effective deployment of technology in educational settings is produced. Fig. 1 illustrates an adaptation of this framework that features the language elements within a specific learning context in conjunction with the other components.

Language context

In this review, we put the emphasis on *language* context, so that aspects of language choice can be understood in depth. By considering the language characteristics of a given context, the other components of the framework can be better applied to support quality learning. Language characteristics may include cultural relevance, breadth of socio-linguistic diversity, attention to and motivation for language learning, as well as broader support for language development within a learning environment. By invoking context, it is important to assure that local stakeholder engagement be taken into account. Typically, information about language characteristics in a given context are provided by local experts, either working with the government or as independent advisers. For example, the Khan Academy utilized support from the state government of Punjab in India to launch their ICT4E platform in the Punjabi language. A select group of teachers localized the content while the state education department set up the necessary infrastructure in school computer labs and provided ongoing teacher support through WhatsApp groups.

Fig. 1 A language-centered ICT4E framework. Adapted from Wagner et al. (2014) and Wagner (2018a,b).

Purposes

The intended purposes of leveraging technology to support learning quality within specific sociolinguistic groups must be described. For instance, one clear purpose would be to provide learners with a choice to develop foundational skills in reading and writing, usually in the home language (L1), and to support the transfer of those skills into an additional language (L2). Language choice was a driving design factor behind a digital early reading program in rural South Africa, which produced positive effects on fluency and comprehension gains as discussed in further detail in the next section (Castillo and Wagner, 2019). Another purpose might be to build upon language- and culturally-specific content to enhance both engagement and comprehension of learning materials such as with the Paraguay example described previously.

End-users

A second component of the framework considers the intended end-users, which could include learners who might have been linguistically marginalized (for instance, due to lack of content in their local languages), displaced populations (either internally or refugee status), and/or differently-abled (cognitively or physically) students. By providing learning materials that are tailored to individual learner abilities as well as access to open-source content and multi-sensory resources, this group of learners may gain access to knowledge that would otherwise be unavailable to them. For example, the iMlango initiative in Kenya aims to improve the educational outcomes of marginalized girls in math using adaptable learning content developed by Whizz Education. Within this project, learners move through a series of math activities that is continuously adjusted, based on data provided by the learners and derived from the accuracy of their responses (Adam et al., 2022).

End-users may also include teachers and parents. Teachers may be introduced to new curricula and learning material to further improve their pedagogical skills (Wagner, 2017b), or to connect them to other teachers to share resources and best practices. In a similar way, solutions can be designed to empower parents to take a more active role in their child's education. Ultimately, the effectiveness of any design solution hinges on the extent to which they are built with specific end-users in mind.

Technology

By leveraging appropriate technologies, whether hardware or software, along with end-users and clear purposes, new options for learning can be undertaken. For example, technology can range from conventional devices like radios and televisions to mobiles and other wearable devices. Also conceivable are digital tools such as automatic transcription, and speech synthesis. Web 2.0 comprises online tools that encourage and support learner's participation in the creation, uploading and sharing of digital artifacts. Examples could include blogs, podcasts, wikis and media editors (e.g., Conole and Alevizou, 2010). ICT4E enterprise Siyavula Education in South Africa, for instance, took into account the available resources and developed a machine learning-powered platform that provides personalized learning content that can be accessed via feature phones. Siyavula is also sensitive to the affordability concerns of its end-users and partnered with Africa's largest telecommunications provider, MTN, to allow learners all over South Africa to access its platform free of charge (Adam et al., 2022).

Design solution

The three circles in Fig. 1 converge in a way that considers each component of the framework with respect to their independent contributions. Together, these components enable the design of educational initiatives that (ideally) draw on optimal integration of technology within the broader language context. Application of this framework in the design and implementation of technology solutions for language diversity and education help provide a more coherent understanding as to how solutions can be scaled and adapted, as well as why some fail to become sustainable over time.

Applying the ICT4E framework in the context of language diversity

We have outlined some approaches to language planning in different country contexts. Here, building again on the cases of India and South Africa, we illustrate how applying the ICT4E framework enables better support of language and education policies.

In India, the StoryWeaver project, initially designed by Pratham, a non-governmental organization (NGO), represents an ICT4E approach aligned with India's three-language policy. This project aims to fill a gap in the quality of L1 material by providing a digital repository of local language stories for children, who have been associated with alienation from schooling and low literacy rates among rural Indian children (ASER, 2019). StoryWeaver's online repository consists of over 45,000 openly-licensed stories in more than 300 languages through national and international collaborations. Due to connectivity limitations, StoryWeaver allows users to download and read stories offline. In 2016, Pratham led a pilot to deliver content in English and Hindi through an audio call back service via phones. In four days, 40,000 calls were placed to 5000 children in the state of Delhi (Butcher et al., 2019). Multilingual content for StoryWeaver was developed by Pratham Books publications, and by users themselves who can upload content.

A second case example is the Bridges to the Future Initiative (BFI), a digital literacy platform created in collaboration with South African NGO Molteno Institute for Language and Literacy. BFI was developed in response to South Africa's Right to Education Policy to promote choice among socio-linguistic minority children. BFI investigated whether access to guided and culturally relevant digital reading content in three home languages could improve early grade reading among primary school children in rural Limpopo, South Africa (Castillo and Wagner, 2019). An important component of this intervention was the development of a multi-media program for early reading in collaboration with local experts to ensure linguistic accuracy and cultural relevance. BFI

offered sequential learning material in multiple L1 languages, providing learners the ability to choose their language of instruction and to engage with the interactive reading material at their own pace. Another underlying factor aligned with the framework was the development of software that could accommodate existing digital resources in participating schools rather than introducing new technology. Findings were associated with nearly three-quarters of a year of additional growth in oral reading fluency, as well as a two-fold increase in reading comprehension among the children who received the ICT-based learning material (Castillo and Wagner, 2019).

By applying the ICT4E framework to these two examples, we can see how a particular purpose (quality content in L1 for India and language choice within multilingual classrooms for South Africa) tailored for a specific end-user (early grade learners) and organized around existing digital resources (such as a free call back service linked to household phones or computer labs already in schools) lead to better learning results. Further, each of the framework components were informed by the overarching language context that included the use of local dialects, motivation for developing the solution (building out a digital book repository or improving early grade reading), and degree of support for the intervention (international collaboration with community and ministry buy-in).

The expanding role of technology in education

Schools can use technology as part of a strategic approach to better engage and support student learning. Here we examine how the expanding use of appropriate technology can help improve the process of learning and teaching, as well as create an inclusive language environment for students and schools.

Student agency and empowerment

The appropriate use of technology creates opportunities for improved student agency. Instead of being passive recipients of instruction, learners in open systems shape their own experiences according to individual goals and interests. This can be achieved by tracking progress along stated goals, and by engaging with the quality of their own work through guided reflection. For instance, many multilingual students struggle to participate on equal terms in the classroom as they confront the dual challenge of mastering grade-level content while learning to learn in L2 (Piper et al., 2016b). Language learners may find it helpful if tasks are broken down into manageable steps such as where hints are provided when needed in their L1 along with the option of rephrasing or translating into L2. In Lebanon, the ICT4E enterprise Augmental offers students the choice to rephrase questions if they are having trouble understanding them. By offering flexible options, such systems give students increased control over key aspects of their educational progress, leading to greater self-efficacy and engagement in their learning (Jääskelä et al., 2021).

Inclusion

Work on the interaction between language and technology sometimes overlooks the diverse needs of differently-abled students. Applying inclusive learning principles like the Universal Design for Learning (UDL) can help to ensure that all learners, regardless of their individual abilities, have the opportunity to use technology for learning (King-Sears, 2009). Embedded assistance features like text-to-speech and speech-to-text, can make learning more accessible to a broader group of learners in multilingual settings (Wood et al., 2018). The game-based learning website Mangahigh has created a text-to-speech engine to convert mathematical notation into readable text that is spoken by the user's browser (Adam et al., 2022).

Another inclusive design practice is access to content in local sign languages and braille for students with hearing impairments or poor vision. For instance, the Ministry of Education in Kenya provided TV and virtual broadcast of stories in Kenyan Sign Language as part of their remote learning policy during school closures due to the COVID-19 pandemic (All Children Reading, 2020).

Content development

When the COVID-19 pandemic led to abrupt school closures, schools faced challenges in providing specialized content and resources for multilingual learners (U.S. Department of Education, 2021). A recent review explored initiatives across LMICs that are incorporating digital personalized learning (DPL) approaches to assist with such challenges (Adam et al., 2022). One central feature is the ability to create learning content alongside local counterparts. This approach improves the ability to generate material that is aligned with curricular standards in multiple languages while ensuring cultural relevance within specific learning contexts. For instance, the ICT4E firm Angaza Elimu engages both local teachers and government in content creation. Learning content for the DPL platform was created by practicing teachers with guidance by a content evaluator from the Kenya Institute for Curriculum Development (KICD). Angaza Elimu program developers then followed the national policy on curriculum design to align the content within the platform.

Adaptability through improved data capture

Technology has made possible the seamless collection and sharing of student data (Wagner, 2018a,b). By combining students' learning preferences, background information (including their home language), and their prior knowledge, content sequences

can be tailored so that they build on and reinforce skills students have previously mastered. Further, the use of digital learning systems can combine predictive analytics with data visualization features that enable a shift in the teacher's role from instructor to learning facilitator. For instance, dedicated dashboards can provide teachers with real-time insight into how their students are performing and allow teachers to identify their strengths and learning gaps. With this information, they can make informed decisions and determine the best course of action to support their students. Pedagogical guidance can also be shared with other stakeholders involved in students' learning, including administrators and parents.

Some systems that deploy AI-based models come with inherent risk that may reproduce inequalities such as underlying biases based on language, gender or ethnicity (Baker and Hawn, 2021). Biases like these are not always apparent in the educational field (Anderson et al., 2019). Stakeholders building AI models thus need to examine the data for evidence of bias. Recruiting a diverse group of experts that are trained to analyze the algorithm output, exposing the algorithm to a more even-handed distribution of examples, can mitigate some biases (Adam et al., 2022). One such initiative is UNICEF's Policy guidance on AI for children (Virginia Dignum et al., 2021), which provides recommendations for building government and private sector policies and systems that uphold children's rights.

Assessment

Technology can also facilitate deployment of hybrid assessments that combine localization with speed and transparency of collected data, at lower stakes (Wagner, 2011). For instance, *Tangerine* is an open-source data collection software that provides insights about student learning by digitizing the Early Grade Reading and Mathematics Assessments (RTI International, 2018). A key benefit of this app is its use of automated data validation features to reduce missing values and other data entry errors common in paper-based assessments. Experimentation in Kenya within a broader digital literacy program was associated with improved monitoring and support to teachers through sustained assessment of learners in early grades (Olubendi, 2019; Strigel, 2014); the app has been deployed in over sixty countries and adapted in more than one hundred languages worldwide.

Conclusion

Multilingualism in education is evolving rapidly as a function of increased globalization, internal and external migration, climate change and more (Wagner, 2018a,b). Concurrently, the rise of new technologies with enabled digital design has led to an increased capability of integrated technology use for improving education through language choice.

Even so, lessons drawn from earlier technology interventions should guide future designs. For instance, early efforts emphasized devices and often overlooked local needs and language context resulting in limited empirical impact (Hinostroza et al., 2014). Despite mixed results in earlier efforts, a growing number of initiatives related to the SDGs emphasize the use of technology as a key aspect of future development efforts (Vinueza et al., 2020). With this growing interest, deployment of digital tools for international education development must center on local context, including language choice.

Further, more emphasis should be placed on leveraging resources to affect change, while disseminating evidence more broadly as a global community. For instance, UNICEF's Reimagine Education Initiative <https://www.unicef.org/reimagine/education> sees digital learning as a component of essential services for all children. The program calls for stronger public-private partnerships to expand connectivity, lower the cost of digital services, and create opportunities for young people to play a role. Similarly, the EdTech Hub (Hennessy et al., 2021) is a global research partnership that aims to disseminate evidence about technology in education to promote more learning across LMICs. While still early in their development, these initiatives, and others like them, have the potential to make a lasting impact.

In this review, we provide a conceptual and empirical basis for the use of technology that supports learning in contexts where the language of instruction is in policy contention in LMICs—usually in spaces where educational content in local languages and dialects has been limited. All the same, current efforts to produce digital solutions that support students learning in multilingual contexts, while currently limited in scope, is gaining in attention. In the coming years, technology will serve an expanding role in improving the processes of learning and teaching while promoting more inclusive and supportive language environments for learning. Such efforts will likely constitute an important contribution to achieving the UN Sustainable Development Goal for education.

Introduction

In the last quarter of the 20th century, sociolinguists and scholars of English language teaching (ELT) began to pay increased attention to diverse varieties of English used in various parts of the world. This burgeoning interest led to the 1981 inauguration of the international journal *World Englishes*, co-founded by Braj B. Kachru and Larry E. Smith, and later the 1992 creation of the International Association for World Englishes (Bolton and Davis, 2018). World Englishes (WE) as a paradigm has destabilized and complexified the notion of English, recognized equal statuses among its different varieties, and questioned the hegemony enjoyed by so-called native speakers of English and English spoken by them (see Bolton, 2020; Kachru, 2013 for an overview of the development of WE).

Even though WE provoked a major paradigm shift in the conceptualization of English, it is facing dual challenges today. On the one hand, despite the large accumulation of research that has shed light on diverse ways people use Englishes and made practical suggestions that aimed to transform traditional ELT, the dominance of Inner Circle standardized English persists in many classrooms around the world. On the other hand, because of its inherently modernist conception of language based on geographical boundaries, WE has been critiqued by scholars who conceive language in a more fluid, mobile, and entangled way. In other words, WE seems to be in a position where its transformative project has not yet unleashed its potential while it is already treated by some as an outdated model.

Given this background, this chapter explores where WE is situated in today's ELT and re-examines its pedagogical utility. We begin by providing a brief overview of the theoretical development of WE and highlighting its relations to neighboring/overlapping disciplinary fields. This is followed by a summary of WE's pedagogical foci, after which we identify some of the major stumbling blocks that impede actualization of WE-informed pedagogy. Next, we highlight select classroom innovations that challenge those stumbling blocks while contextually applying WE elements to instruction. We then respond to a critique of WE while discussing a pragmatic and critical approach to WE that puts its theoretical limitations to use for pedagogical purposes.

World Englishes and its neighboring/overlapping paradigms

Since the 1980s, the diverse and complex sociolinguistic realities of English and its users in a postcolonial and globalizing world have attracted scholarly attention as signified with WE. The impetus of such exploration dates to when WE reconceptualized English use and users in international contexts, challenging the monolithic conception of English restricted to British and American

*Corresponding author

standardized varieties. One of the influential conceptual models was offered by Kachru (1985), which visually presented the global diffusion of English, drawing boundaries between three concentric circles: the Inner Circle, where English is the primary language (the USA, the UK, Canada, Australia, and New Zealand), the Outer Circle, where intranational and institutional uses of English were the result of colonization by Britain and the United States (e.g., Nigeria, India, and the Philippines), and the Expanding Circle, in which English is learned as a foreign language and mainly used for international communication (e.g., Brazil, China, and Russia).

This boundary-making resulted in the pluralization of English to Englishes and was an inevitable response to the increased complexity surrounding the roles and users of English in the world in the 1980s and 1990s. It was also an attempt to claim legitimacy and recognition of English varieties that had been traditionally marginalized. As Kachru (1992) writes, "The result of [English's global] spread is that, formally and functionally, English now has multicultural identities. The term 'English' does not capture this sociolinguistic reality; the term 'Englishes' does" (p. 357). Kachru's early articulation of Englishes became the seed for a paradigm shift. This is part of a broader politics of recognition since "claims [to recognition] often take the form of calling attention to, if not performatively creating, the putative specificity of some group, and then of affirming the value of that specificity" (Fraser, 1995, p. 74). In discussions of English, the traditional classification of English varieties predicated on native and non-native speaker dichotomy such as English as native language (ENL), English as a second language (ESL), and English as a foreign language (EFL) has thus been replaced, or at least complemented, by WE with inclusive plurality of language varieties at its core (Bolton, 2020).

As a paradigm, WE not only pluralized the English language by delineating provisional boundaries, but it also facilitated pluralization of disciplinary space in the study of English—paving the way for the development of new conceptual approaches or paradigms. English as an International Language (EIL) is one such example; Sharifian (2009) explains that EIL is "a paradigm for thinking, research and practice" in TESOL, SLA, and the applied linguistics of English, whose themes are centered on "its recognition of World Englishes, regardless of which 'circle' they belong to" (p. 2). EIL stresses diverse use of English from Kachru's three circles as international and intercultural communication, while WE studies are often associated with explorations and re-evaluations of Englishes primarily in Outer Circle contexts (Hino, 2018; Saraceni, 2015).

Another WE-related paradigm is English as a Lingua Franca (ELF), although ELF is often discussed in parallel to WE as an independent entity to represent a different theoretical approach to English varieties. ELF, defined as "any use of English among speakers of different first languages for whom English is the communicative medium of choice, and often the only option" (Seidlhofer, 2011, p. 7), explores the function and validity of different Englishes in international settings with its primary focus on Expanding Circle users of English. Jenkins (2018) explains that ELF was initially deemed "an ideological and linguistic extension of WE," (p. 12) and now as a complementary (rather than competing) paradigm, acknowledging Kachru's (1992) work as the key influence on ELF.

Critical work in sociolinguistics and applied linguistics concerned with translingual practice (Canagarajah, 2013)—such as linguistic hybridity (e.g., Otsuji and Pennycook, 2013) and translanguaging (e.g., Garcia, 2009)—also furthers inquiries across scholarly circles, challenging the notion of boundaries mobilized by the WE paradigm to pluralize English. Otsuji and Pennycook (2010) claim that "there need to be alternative ways of understanding diversity other than pluralisation" (p. 251) and argue for an approach that centers the complexity of local language practices and eschews any naïve associations between a language user and specific places, sites, backgrounds, or identities.

Responding to such diversification of disciplinary fields associated with multi/plural turn of sociolinguistics and applied linguistics research (see Kubota, 2015, 2016), there has been an effort to integrate WE, EIL, ELF, and the translingual paradigms into a comprehensive umbrella term called Global Englishes (GE). Rose and Galloway (2019) define GE as "an inclusive paradigm that embraces a broad spectrum of interrelated research that has come before it and emerged alongside it" (p. 6). Indeed, the emergence of this umbrella paradigm clearly shows the proliferation of WE-related/informed paradigms. New paradigms are often the result of critique, and WE is no exception. The three-circle model is limited in the ways it can account for the range and complexity of language practices in today's world. However, WE has long served as a catalyst for dialectic explorations, across scholarly circles, of linguistic diversity, resisting the power of monolithic linguistic normativity. As Bolton (2020) observes, this openness and flexibility to scholarly inquiries, new ideas, and innovation is the foundation of WE.

WE and pedagogy

The WE paradigm opened up disciplinary explorations pertaining to diverse use and users of English, with rigorous scholarly activities signifying postcolonial resistance to Inner Circle linguistic and cultural norms. The impact and influence of the WE paradigm on academia, however, was akin to a ripple effect: when the "stone" was thrown into the water, the primary target that was aimed for was English language pedagogy. Indeed, ELT "has always been a very central—and, possibly, the central—preoccupation" (Saraceni, 2015, p. 8) in WE studies. Teaching of WE can primarily be centered on responding to and addressing fallacies about use and users of English in the world context. These fallacies include the notions that: outside the Inner Circle, English is learned to communicate with native speakers of the language; English is learned to understand American or British cultural values; the goal of English learning and teaching is predicated on the native-speaker model which thus reduces non-native varieties of English to interlanguage as lacking or decaying; and native speakers play significant roles in the teaching of English (Kachru, 1992). Calling for this attitudinal and methodological paradigm shift in the classroom, Kachru (1992) proposed the following six foci for teaching advanced students and training professionals (pp. 360–361, emphases original):

1. Sociolinguistic profile: an overview of English in its world context with discussion of selected major varieties, their users and uses. A clear distinction to be made between the use of English in a monolingual society, as opposed to a multilingual society; and its implications (e.g., mixing, switching).
2. Variety exposure: an exposition of the repertoire of major varieties of English, native and non-native: their uses and users, specific texts related to various interactional contexts, shared and non-shared features at different linguistic levels.
3. Attitudinal neutrality: for teaching purposes, one might focus on one specific variety and at the same time emphasize *awareness* and *functional validity* of other varieties.
4. Range of uses: the functional appropriateness of the lectal range of varieties within a specific a specific variety (e.g., from educated varieties to the pidgins and basilects).
5. Contrastive pragmatics: the relationships of discoursal and stylistic innovations and their relationships to the local conventions of culture (e.g., strategies used for persuasion, phatic communion, apologies, condolences, and regrets).
6. Multidimensionality of functions: the linguistic implications of the functional range, as in, for example, the media, in literary creativity, in administration, in the legal system.

It goes without saying that this was not intended as a comprehensive list for teaching WE in the classroom; it needs to be contextually sensitive and relevant to local learning and teaching communities of practice, such as goals and objectives, students' learning and communicative needs, students' and teachers' sociolinguistic backgrounds which may or may not be shared, and so forth. Indeed, teaching from a WE perspective in ELT is challenging not only because of the conceptual and methodological innovation required (Kachru, 1992), but also because it presents such a fundamental challenge to established attitudes toward "standards" for the teaching and learning of English—despite its relevance for the changing realities of English use and users. The next section discusses existing "stumbling blocks" which stand in the way of pedagogical application of WE.

Stumbling blocks

As was already discussed, WE has the potential to transform the traditional, Inner Circle and native speaker-based ELT to a more inclusive field by emphasizing diversity among Englishes for learners. However, since such transformation requires several fundamental changes in various domains in ELT and society at large (Matsuda, 2012a; Matsuda and Friedrich, 2011; McKay, 2002), it inevitably meets challenges. In this section, we summarize these challenges as ideological, sociopolitical/structural, practical, and scholarly "stumbling blocks" that impede realization of WE-informed pedagogy. It is important to note that these four domains are not meant to be discrete and exhaustive. Rather, we use them as a workable framework to clarify the existing issues for researchers, practitioners, and policymakers to work on.

Ideological domain

Various ideologies related to language, especially native-speakerism and normativism, are extremely powerful stumbling blocks in many ways (Holliday, 2006, 2015; Kubota, 2018b). For example, native-speakerism — the belief that "native-speaker" teachers represent a 'Western culture' from which spring the ideals both of the English language and of English language teaching methodology" (Holliday, 2006, p. 385) — penetrates classrooms, employment policies, national- and supra-national education policies as well as ELT scholarship (Cook, 2007; Davidson, 2006; Hashimoto, 2013; Holliday, 2006; Kubota, 2018a; Kumaravadivelu, 2016; Phillipson, 1992). Here, "native English speakers" are often ideologically and discursively constructed as white speakers from Inner Circle communities (Kang and Rubin, 2009; Kubota, 2018b, 2021). Native-speakerism thus predominantly gives white native speakers from Inner Circle communities and Englishes spoken by them symbolic status (e.g., being recognized "authentic" or "intelligent") as well as material benefits (e.g., higher salary or chance of employment) both within and outside the English-speaking West.

In relation to realization of WE-informed pedagogy, native-speakerism leads to general assumption that the goal of learning English is to be like or to communicate with native speakers (Berns, 2006; Cook, 2007), learners' and teachers' preference for Inner Circle varieties of English over other Englishes (Matsuda, 2003; McKenzie, 2010), or teachers' association of standard English with Inner Circle standardized varieties of English, even when they think teaching different varieties of Englishes is desirable (Mimatsu, 2011). These phenomena denigrate the symbolic status of the Outer Circle and Expanding Circle Englishes, and thus are an impediment for those varieties to be accepted by teachers, learners, policy makers, and publishers.

In addition to native-speakerism, normativism, which diminishes English that is deviant from its "conventional" or "standard" form, stands as a significant stumbling block. This is especially prevalent in writing, both in classroom assignments and high-stakes academic writing such as publishing or grant proposals. Due to the strong normativism, learners often receive lower grades in writing classes and scholars lose chance to get their work published for their "incorrect" use of non-standard form of English, forcing both learners and scholars to sustain the hegemony of standardized English (Davila, 2016; Heng Hartse and Kubota, 2014; Matsuda and Matsuda, 2010; O'Regan, 2021; also see "Practical domain" and "Scholarly domain" below).

Sociopolitical and structural domain

A number of stumbling blocks elaborated in this section are sustained and reinforced due to sociopolitical and structural factors, especially neoliberal political economy, teacher education, assessment practice, and political nature of educational policy.

Current language education policy and practices as well as scholarly activities cannot ignore the influence of neoliberalism (Ricento, 2015), which is an economic and political theory that presumes that human well-being can be best advanced through individual entrepreneurial freedoms and deregulation of markets (Harvey, 2005).

In terms of WE-informed pedagogy, the neoliberal political economy functions as a stumbling block by sustaining the symbolic value of standardized English at least in three ways. First, as neoliberalism endorses borderless economy and efficiency, it valorizes English as “the” international language for global communication for business and strengthens the belief that English proficiency brings economic return (Kubota, 2011, 2018b; Ricento, 2015). In turn, these perceived values of English influence (supra-) national policies and educational practices, promoting English language education worldwide (McNamara, 2011; Sayer, 2015). Although neoliberalism does not specifically endorse “standard” English in theory—rather, it endorses the diversity of people and cultures as a catalyst for strengthening economic competitiveness (Kubota, 2016)—it inevitably sustains the hegemony of standard English because “English” in ELT practices and policies still predominantly means “standard English,” as recent studies continuously suggest (e.g., Boonsuk et al., 2021; Cushing, 2021a,b; Galloway, 2017; Rose and Galloway, 2017). Second, as neoliberalism holds scholars and institutions where they work accountable and competitive, it makes scholars complicit with sustaining the hegemony of standardized English because it is the de facto universal medium of writing and presenting in academia (see “Scholarly domain” below). Third, neoliberalism also forces people to acquire a bundle of skills to keep their employability and competitiveness (Kubota and Takeda, 2021; Urciuoli, 2008). This accelerates the need for large-scale standardized assessments like TOEFL or IELTS, whose benchmarks are largely Inner Circle-based. The issue of assessment is elaborated further below.

Teacher education plays a vital role to transform education because it can influence teachers, each of whom will then influence a number of students and potentially local school curricula (Matsuda, 2017). However, many teacher education programs are still Inner Circle- and standardized English-based (Bayyurt and Sifakis, 2017; Biric Deniz et al., 2020). Transforming teacher education is indeed a daunting task and meets a number of stumbling blocks as it is deeply embedded in the existing social structure and connected to people’s beliefs about English. For example, there is not enough guidance for teacher educators despite recent practical works that support WE-informed pedagogy (Dogancay-Aktuna and Hardman, 2017). In addition, teachers believe that they are the “custodian” (Bayyurt and Sifakis, 2017, p. 6) of standardized English, or they think that WE-informed pedagogy is desirable but not necessary (Matsuda, 2009). Furthermore, teacher candidates are reluctant to fundamentally change their traditional understanding of English to something more fluid, unstable, and heterogeneous like WE or EIL, as they might see such change as a dismissal or denial of the past effort and investment in English learning (Matsuda, 2017).

In addition to teacher education, another structural issue is assessment, which serves as a particularly strong mechanism to set, maintain, and reinforce the linguistic norms (Davidson, 2006; Hu, 2018; Shohamy, 2006, 2011). Moreover, the trend to utilize global assessment tools like TOEFL or IELTS, which is largely motivated by neoliberal pressure that holds people accountable with measurable, comparable, and globally transferable scores, has caused two problems. The first is that large-scale tests like TOEFL often use Inner Circle Englishes for test items and scoring criteria, reproducing and imposing such Englishes as a global norm. The second is that large-scale tests are often developed for specific purposes (e.g., TOEFL is to assess learners’ academic English ability to study in North American context), they may not be suitable to local learners’ needs (Chalhoub-Deville and Wigglesworth, 2005; Davidson, 2006; McNamara, 2011).

Although theoretical discussions have been conducted on linguistic inequality in assessment (e.g., Brown, 2014; Canagarajah, 2006a; Hu, 2012, 2018), transformation in practice rarely happens for three reasons. First, because test developers need to establish construct validity, they need English that is well-described, which necessarily becomes the traditional Inner Circle Englishes (Brown, 2014). Second, test-making is increasingly becoming a political act, and policy makers often decide specific benchmarks against which test-takers are evaluated, such as the Common European Framework of Reference (CEFR) (McNamara, 2011). McNamara (2011) argues that although test developers used to define benchmarks using the latest theories on language, communication, and other related areas, this “‘thinking stage’ of test development has now been removed” and replaced with “complex policy procedures” (p. 502). He shows how CEFR has pre-determined standards of language proficiency—some of which assess the proficiency of a speaker vis-à-vis that of native speakers—and how those policy-driven standards influence society to a large extent. Third, and relatedly, benchmarks, especially large-scale, influential frameworks like CEFR, are deeply embedded in existing social structure, thus changing them would be naturally challenging as multiple administrative and legislative procedures are involved (McNamara, 2011).

McNamara’s (2011) insights on sociopolitical aspects of assessment are important, as they hold true in educational policy in general, not only assessment. This is another stumbling block to realize WE-informed pedagogy. Given that calling for WE-informed pedagogy is “quite radical” (Matsuda, 2012a, p. 6), transformation of the current Inner Circle-based teaching model requires not only practitioners’ micro-level efforts, but also result-oriented activism that impacts national- and supra-national-level policy. Since policymaking is largely driven by politics, not always rationality (Edelman, 1988; Wodak, 2011), scholars’ rational critique itself may not lead to policy change. Thus, WE scholarship for transforming policies and practices needs to break the scholarly bubble and reach out to and work together with a wider audience. This leads and is connected to stumbling blocks in the scholarly domain (see “Scholarly domain”).

Practical domain

The practical domain is perhaps the biggest hindrance to realize WE-informed pedagogy. First, since the school systems still operate within standardized curricula to a great extent, teachers have almost no choice but to rely on traditional ELT. That is, while WE

scholarship appreciates and describes the diversity of Englishes in society, thus questioning such notions as norms and standards, traditional teaching still tends to rely on them because they are useful—almost necessary—to conceptualize teaching contents, set goals, create materials, and assess learning.

Second, as mentioned earlier, normative ideologies of English are especially pervasive in academic writing. This is despite the recent popularity of translanguaging, which problematizes the view that students' multilingual competence is a sum of abilities in named languages that are separated by fixed linguistic boundaries (e.g., [García and Kleyn, 2016](#)). Instead, translanguaging valorizes students' agentive maneuvering of diverse linguistic repertoires that are available to them. Yet, academic writing in English typically expects students to follow established conventions. Any deviation can risk negative consequences especially in high-stakes tasks, such as writing for tests, publications, grant proposals, job applications, and so on ([Heng Hartse and Kubota, 2014](#)). Thus, the popularized pedagogical approach to translingualism has been critiqued by second language writing professionals, who are skeptical of the academic and professional viability of this approach for students who are second language writers in English (see [Silva and Wang, 2020](#)).

Third, even if practitioners desire to practice WE-informed pedagogy, they are often not supported materially, meaning that there is a dearth of resources to guide this type of pedagogy ([Galloway and Rose, 2018](#); [Matsuda, 2012b](#)). Researchers point out that materials published by large publishers continue to feature Inner Circle Englishes and speakers ([Kumaravadivelu, 2016](#); [Matsuda, 2012b](#); [Yamada, 2015](#)), who are also often racialized as white ([Kubota, 2018b, 2021](#)). ELT scholarship has seen proliferation of theoretical critiques against traditional, Inner Circle-based ELT over the last 50 years but teaching practices and publishers of teaching materials have not kept up with the speed of such theoretical development.

Finally, even if teachers were able to include some elements of WE in their classroom (see [Stepping stones toward the changing paradigm](#) section), their practices may become simplistic and superficial because of time constraints, lack of institutional or material support, parents' demands for traditional Inner Circle-based ELT, and so forth. This reality hinders a progressive implementation of WE-informed pedagogy, because it ironically stigmatizes WE-informed practitioners—despite their good intentions—as essentializing a certain variety of English through their simplistic or superficial representations. This means that practitioners could be targets of scholarly criticisms either for continuing traditional ELT or for incorporating elements of WE in the classroom if their practices are simplistic and superficial.

Scholarly domain

Although the significance of theoretical advancement in WE scholarship is unquestionable, scholars too have their own stumbling blocks, and can be complicit in reifying the status quo in the following ways. First, some scholars critically point out that much discussion on WE-informed pedagogy remains abstract and unactionable for practitioners and policymakers ([Kubota, 2018b](#); [Matsuda, 2012a](#); [Matsuda and Friedrich, 2011](#)). Others also critique how theoretical discussions of the social necessity for WE-informed pedagogy often take place without insights and perspectives from local classrooms ([Galloway and Rose, 2018](#); [Matsuda, 2012a](#); [Tupas, 2010](#)). This is an unhealthy situation because the lack of consideration of local contexts prevents practitioners from integrating the theoretical knowledge into their everyday practice.

Second, as was already mentioned, scholars can be complicit with sustaining the hegemony of standard English due to neoliberalism ([Kubota, 2016](#); [O'Regan, 2021](#)). This is because most scholars work in institutions operating under the neoliberal regime, which champions "more and faster" as a basic principle and care about international rankings and journal impact factors for self-branding and accountability purposes. Thus, scholars are evaluated against how much they published in prestigious journals and how much grant funding they won. Here, a long-standing, unquestioned, and default medium of writing is standardized English ([Heng Hartse and Kubota, 2014](#); [O'Regan, 2021](#)), and the chances of getting accepted for publication and winning grants significantly drop when the work is written in non-standardized form of English. Therefore, ironically, even WE scholars might need to be complicit with this long-standing hegemony of standardized English to make their voice heard in the first place.

Third, scholars' critiques tend to remain within academia ([Kubota, 2018b](#)). In order to disrupt the existing hegemony sustained by Inner Circle standardized English, scholars should seek ways to reach out to the wider public and disseminate their findings, thereby informing practitioners with practical suggestions, communicating with policy makers, or making efforts to debunk popular ideologies about English language.

Fourth, scholarly activities also tend to be confined within certain conceptual orientations. As [Matsuda and Matsuda \(2018\)](#) pointed out, many scholars who are interested in the plurality of English align with their own theoretical orientation without much communication with each other. However, regardless of their conceptual differences, WE, ELF, EIL, GE, and translingual scholars all acknowledge that the messiness of English(es) cannot be captured by monolingual ideology, aim to move away from the native-speaker norm, and advocate equal rights for all languages ([Alsagoff, 2012](#); [Matsuda, 2017](#)). Resistance to the established teaching practices and policies entails a "major overhaul" ([Matsuda and Friedrich, 2012](#), p. 25) of the current system and belief, and if so, like-minded scholars should work in collaboration, not in isolation, for that same goal.

Stepping stones toward the changing paradigm

Despite these existing limitations and obstacles, ELT practitioners' efforts to contextually apply WE in the classroom continue until today, and have been documented across [Kachru's \(1985\)](#) three concentric circles: the Inner Circle (e.g., [Henderson Lee and Pandey, 2021](#); [Kubota, 2001](#); [Sharifian and Marlina, 2012](#); [Tardy et al., 2020](#)), the Outer Circle (e.g., [Ali, 2015](#); [Sung, 2015](#)), and the Expanding Circle (e.g., [Bayyurt and Altinmakas, 2012](#); [Chang, 2014](#); [D'Angelo, 2012](#); [Galloway and Rose, 2018](#); [Lee, 2012](#); [Rose and](#)

Galloway, 2017). These reports on how the WE paradigm is used in classroom settings can be seen as stepping stones that help bridge existing gaps between WE's theoretical potential and its pedagogical application. The stepping stones represent practitioners' work to bring about a WE-informed pedagogical paradigm shift, necessitating both "an entirely different set of assumptions than the teaching and learning of any other second or foreign language" (McKay, 2002, p. 1) and "a thorough re-conceptualization and a thorough re-organization of knowledge systems" (Kumaravadivelu, 2012, p. 14). In what follows, we will thematically showcase WE-informed/relevant pedagogical innovations made by teacher-scholars and highlight subsequent trends and implications for ELT.

Awareness-raising

As Matsuda (2020) argues, what both students and teachers increasingly need today is more "the metaknowledge of the linguistic diversity than the specific formal and functional rules of particular varieties" (p. 688). Indeed, the most apparent pedagogical aspect interwoven into Kachru's (1992) six proposals for classroom innovations are directly concerned with awareness-raising regarding WE. Awareness-raising instruction has often included deliberate exposure to English varieties and the validation of fluid, rather than prescriptive, uses of English.

Galloway and Rose (2018) report on a classroom-based research study in a Japanese university that investigated the instructional efficacy of a learning task on GE. The task aimed to raise awareness of GE through exploring a regional variety of English chosen from Kachru's concentric circles or investigating the use of ELF for a specific purpose. The students investigated an English variety of their personal choice using the library, internet, and other resources to conduct a ten-minute presentation using visual aids. According to Galloway and Rose, students' written reflections on the task suggest that the activity was positively received; it enabled students to discover and reflect on the linguistic features, functions, and historical development of the varieties they had selected. Reflections on language and identity, standardized English, and Indigenous languages were also observed.

Sung's (2015) study is another example that focuses on awareness-raising activities in an Asian classroom context. Sung implemented a GE-oriented component to raise students' awareness of WE variation in a university English course in Hong Kong. The classroom activities ranged from listening tasks such as accent identification of different varieties of English to discussion tasks regarding standardized English, native speakers, and ELF communication. Sung reported that students welcomed these awareness-raising activities, which prompted them to think through different varieties of English, the reality of English use in the world, issues surrounding (non)native speakers in intercultural communication, and so forth. However, the study also showed that although these activities heightened their awareness of GE, most students continued to hold negative perspectives toward non-native varieties of English, exemplifying the pedagogical conundrum of challenging the native-speaker norm within a limited instructional time.

Attempts to direct students' attention to WE in the classroom are not only made for non-native learners of English in ELT contexts but also for native speakers of English. Arguing that Inner Circle native speakers of mainstream English should also share the responsibility for successful communication, Kubota (2001) details an instructional unit that exposed American high school students to inter/intra-national varieties of English. The unit invited them to think through the global spread of English, the reality and difficulty of second language acquisition, and their responsibility and available strategies for communication with WE speakers. Instructional modes and materials included lectures, group work, whole class discussion, video clips, reflective writing, and interaction with guest WE speakers. Based on the results of the pre- and post-surveys, Kubota observed positive change in students' attitudes toward and comprehension of WE, their understanding of speech samples, as well as the difficulty of second language acquisition. However, significant improvements in perceived quality of speech samples, perceived personal traits of WE speakers, and desire to communicate with them was not confirmed. Furthermore, some students made xenophobic remarks, drew on problematic stereotypes, and showed ethnocentric biases during in-class discussions, indicating a challenge for classroom intervention. The results of this project offer pedagogical implications that highlight "the necessity of affirming linguistic diversity at all educational levels and creating a pedagogical environment conducive to developing critical consciousness on the global spread of English" (Kubota, 2001, p. 62).

(Un)learning language ideology

As the WE paradigm questions and challenges the linguistic norms established exclusively by Inner Circle varieties of English, critical discussions for decentering and (un)learning standardized language norms have been incorporated into the classroom. Such discussions are often an extension and/or application of awareness-raising instruction through exposure to varieties of WE, and challenge students to critically engage with issues surrounding language and power.

A study by Chang (2014) reports on the pedagogical impact of incorporating critical issues surrounding WE into a university-level course in Taiwan. Using activities that included lectures, discussions, student presentations, reflective writing, and a final exam, the WE course invited students to reflect on various issues such as standard language ideology, the "native" and "non-native" dichotomy, as well as the global dominance of English and its influence on their community. According to Chang, students' reflections suggested that the course had helped them redefine the purpose of language learning, while increasing their open-mindedness toward different varieties of English and prompting them to challenge the native-speaker norm. One student wrote, "You do not have to care about the red lines under it when we type the word Englishes on MS word" (p. 25), implying the course had impacted their beliefs about the legitimacy and ownership of English. The pedagogical impact elaborated in the study in the form of student reflection was overwhelmingly positive, suggesting the possibility for incorporating critical issues into the ELT classroom, such as language ideology and power.

Rose and Galloway (2017) detail a debate activity conducted in a university-level course in Japan, which used the “Speak Good English Movement” in Singapore as a topic to debate on the standardized language ideology. The movement encouraged Singaporeans to speak and write in standardized English, rather than in Singlish or a Singaporean variety of English, because it was not perceived as intelligible enough in the globalized world. The students were invited to argue for or against the movement. Pre-debate activities included a research task that encouraged students to gather evidence from newspaper articles and online videos to support their argument. After the debate activity, students shared their accounts of their positions and beliefs in the form of written reflections, which were used as a data source to gauge the impact of this activity on students’ awareness of language attitudes and ideologies. Rose and Galloway concluded that the use of the “Speak Good English Movement” for the debate successfully enabled students to increase their awareness of the sociolinguistic profile of Singaporean English, to think through its cultural significance for Singaporeans, and to challenge standardized language ideology in the process. This classroom innovation is a good example of how authentic WE-relevant issues can be introduced into ELT classrooms in which the native-speaker norm perpetuates, and can raise students’ (and teachers’) awareness “that standards are imagined benchmarks, and that it is the actual use of a language that indicates its legitimacy” (Rose and Galloway, 2017, p. 300).

Writing

Writing is one of the linguistic domains where standardized English has prevailed (e.g., Gupta, 2006). However, scholars continue to contest the pervasive preference for literacy skills predicated entirely on standardized English, advocating WE-informed pedagogical spaces not only in creative writing (e.g., Lim, 2015) but also in more conservative genres such as academic writing. Canagarajah (2006b) argues that students require a linguistic and strategic repertoire that allows them to “shuttle between communities” (p. 593) in socially situated ways, as opposed to striving for a single standard form of language. This can be achieved by a literacy practice of what Canagarajah calls code-meshing, a strategy of merging local variants with standardized English in rhetorically effective ways in academic writing. Canagarajah details the pedagogical use of code-meshing, through the use of writing models that employ African American Vernacular English in texts for multilingual students to understand how linguistic creativity can be performed in their writing. The notion of code-meshing is not simply mixing or switching back and forth different varieties of a named language or different languages. It symbolizes the ways writers shuttle between their available linguistic resources rather than moving between discrete and bounded linguistic categories (Canagarajah, 2013). This conceptualization of language, which questions linguistic competence defined by fixed linguistic boundaries, is consistent with the notion of translanguaging which has become popular in recent years (e.g., Cenoz and Gorter, 2020).

Calling for the development of global literacy responsive to the realities where students socially engage in the multiplicity of English, Matsuda and Matsuda (2010) offer guiding principles for teachers who wish to implement WE-informed writing pedagogy in the classroom. They include the teaching of (a) the dominant language forms and functions (so that students understand the privileged status certain English varieties enjoy and so that they can appropriate them when they need to); (b) the nondominant language forms and functions (so that students understand deviations are employed in the writing in socially meaningful ways; etc.); (c) the perceived boundaries between variations and errors; (d) the strategies that can be employed when using nondominant forms in socially acceptable ways; and (e) the potential risks involved (so that students become sensitive to how and when deviations from the norm can/cannot be effective especially in the dominant discourse they negotiate). ELT practitioners’ efforts to contextually apply such principles and strategies to L2 writing classrooms have been made to this date.

Henderson Lee and Pandey (2021) report on an instructional unit for multilingual writers in an American university, which incorporated WE texts as a catalyst for nurturing global literacy. Using a TED Talk called *3 Ways to Speak English* (Lyiscott, 2014) and a text from *Rotten English: A Literary Anthology* (Ahmad, 2007) as stimulus WE materials, the authors showed that students were able to raise their awareness about how and when nondominant forms can rhetorically strengthen their written texts, while positively impacting their beliefs and attitude toward language varieties. The conclusion of the study offers a list of potential resources that can navigate WE-informed writing instructions.

Tardy et al. (2020) is another recent study which took place in a course for multilingual writers in an American university. Combining content-based and language and genre awareness approaches, the course engaged students in exploring WE concepts such as standardization, nativeness, intelligibility and identity, and dominant and nondominant varieties. The article elaborates on various activities used for the course, one of which is inviting students to write an academically argumentative response to Matsuda and Matsuda’s (2010) article (mentioned above). Writing a response to scholars’ suggestions allowed students “to share their views on English language norms, validating their experiences and values” (p. 7), indicating the possibility of using scholarly articles on WE as stimulus texts in advanced literacy instruction.

Communication strategies

The teaching of pragmatic and linguistic strategies has long been explored in ELT since its early days (Dörnyei, 1995). Traditionally, such communication strategies have been regarded as verbal and non-verbal techniques to compensate for communicative breakdowns or increase communicative effectiveness (Canale, 1983). They have been discussed as part of strategic competence that constitutes communicative competence from the perspective of second language teaching (Canale and Swain, 1980). In today’s globalizing world where diverse users of English bring their linguistic repertoire into a specific communicative space, communication strategies have been reconceptualized as mediating strategies necessary for crossing linguistic and cultural boundaries. Canagarajah (2007, p. 236) lists different interaction practices where varieties are negotiated and communication strategies play a mediating role:

- Code-switching, crossing (Rampton, 1995);
- Speech accommodation (Giles, 1984);
- Interpersonal strategies: i.e. repair, rephrasing, clarification, gestures, topic change, consensus-oriented, mutually supportive (Gumperz, 1982; Seidlhofer, 2004);
- Attitudinal resources: i.e. patience, tolerance and humility to negotiate differences (see Higgins, 2003).

Stressing the relevance of communication strategies for speakers who use different varieties of English (or other languages), Canagarajah calls for a pedagogical focus on developing such strategies as opposed to (standardized) rules and conventions. Similarly, Kubota (2012) and Kubota and Takeda (2021) maintain the need to teach students communication strategies for border-crossing communication, which is “active, critical and reflective engagement in communication across diverse ethnic, racial, linguistic and socioeconomic differences” (Kubota, 2012, p. 63). Such communication contexts include both ELF situations where English serves as a common language and other situations where English does not. Furthermore, students may interact with L2 users of their L1. Border-crossing communication highlights the importance of accommodation skills, such as gauging interlocutors’ linguistic repertoires, supportive listening, paraphrasing, and adjusting speech speed. The emphasis on communication strategies rather than a sole emphasis on linguistic forms is also a response to reconceptualization of communicative competences in socially situated ways as informed by the WE and related paradigms. As Canagarajah (2007) argues, communicative proficiency in light of such paradigms requires being able to negotiate linguistic differences, where communication strategies are expected to come into play.

Responding to the critique of WE: pragmatic and critical utilization of boundaries

Having illustrated some of the pedagogical innovations and suggestions regarding WE, we would like now to turn to the core critique against WE: problematizing its reification of varieties based on geographical boundaries. In what follows, we examine the main claim of this critique and argue for pragmatic and critical utilization of WE in which even the theoretical limitations can be rendered as pedagogical opportunities.

WE contains an inherently modernist conception of language that associates certain linguistic features with geographical boundaries. Through its nation-based categorization, WE inadvertently gives an impression that those varieties are discretely codifiable and that the usage of English is somewhat uniform within those categories (Bruthiaux, 2003). With this, rather than fully decentralizing the standardized English, WE preserves the idea of centrality vis-a-vis its own boundary-making: it reproduces the idea that there are “typical” usages of the named English variety that are recognized as linguistically legitimate because they are frequently and systematically used by a certain linguistic community, while leaving “non-typical” usages unrecognized. Regardless of how extensively sociolinguistic data are collected, due to the generative nature of language use, utterances and writings that deviate from categorical norms theorized by the WE framework will continuously be produced. Thus, WE struggles to deal with deviations within a named variety. This theoretical limitation not only makes it difficult for WE to adequately account for increasing mobility and fluidity of semiotic practices in the globalizing world, but also risks reproducing the system of domination and oppression it purports to disrupt. As Pennycook (2007, p. 21) stated, “by focusing centrally on the development of new national Englishes, the world Englishes approach reproduces the very linguistics it needs to escape.”

Nonetheless, at the pedagogical level, WE continues to provide a useful framework as long as it is adopted pragmatically and critically. Pragmatic adoption of the WE framework provisionally utilizes the boundaries of varieties while recognizing the contingency and contestedness of drawing such boundaries. As we discussed earlier, strategic use of boundaries enables one to claim legitimacy and (sociopolitical) recognition of diverse ways people use English and effectively highlight those uses in classrooms. If we dismiss the existence of languages and their varieties because they are “the inventions of social, cultural and political movements” (Makoni and Pennycook, 2007, p. 2), we lose the ground for claiming their rights and ensuring equitable representations of them (MacSwan, 2020). This is a structurally similar issue created by the tensions between modernist and postmodernist forms of critique: whereas the former consolidates identity categories for emancipatory struggles, the latter dissipates those categories and rejects the totalizing tendency of the former (Pietikäinen, 2016; Takeda, 2022).

Yet, the pragmatic approach we advocate in this chapter renders these tensions into pedagogical opportunities. With the former, by tangibly identifying diverse varieties of English, we argue that teachers are better positioned to ensure the inclusivity of teaching materials and instructions. The pedagogical approaches we discussed above (e.g., Bayyurt and Altinmakas, 2012; Chang, 2014) adopt the WE framework to teach students not only about diverse varieties of English, but also about language ideologies and systemic inequalities perpetuated by Inner Circle norms. Without provisional acceptance of boundaries, linguistic differences are “flattened” (Gilyard, 2016), making it difficult to unsettle Inner Circle norms while claiming the recognition and identity of marginalized Englishes. Critical discussions of inequalities based on race, gender, nationality, and so on in association with language (Kubota, 2020) can also be made possible by such a utilization of boundaries.

While WE provides a useful framework for teachers to ensure diverse and inclusive representations of English varieties in the classroom, it must be adopted critically. Because any form of boundary work involves exclusion, uncritical utilization of the WE framework risks linguistic essentialism and delegitimization of English usages that are considered “irregular” within a given variety. In fact, WE typically claims legitimacy of a certain English variety by highlighting its systematicity and regularity or what Lee (2017) calls “frequency premise.” According to this premise, Lee states:

if a particular feature occurs frequently enough, even if it is a deviation from mainstream norms, it warrants recognition and legitimacy. The frequency premise is foundational to descriptivist approaches to language and is what drives the practice of linguistic codification (p. 28).

Although it is undeniable how this approach has successfully claimed the legitimacy of certain English varieties like Philippine English (Tupas, 2004), it simultaneously reinforces the authority of the standard—in this case, the variety of English used by educated elites in the Philippines. Because the claim of legitimacy in this way follows “the criteria of dominant apparatuses of authoritative English,” Lee (2017, p. 31) argues, “the frequency premise thus reifies the standards by focusing on the deviations from the very standards as such.”

Thus, uncritical adaptation of WE could inadvertently reinforce the idea of standards and delegitimize usages that fall outside of the boundaries. In this sense, some of the pedagogical approaches above could be potentially problematic. For instance, some of those pedagogies involved identifying accents of different varieties of English and learning about their sociolinguistic profiles. If those activities are implemented in such a way to solidify students’ idea of the varieties introduced without simultaneous destabilization of the boundaries, they risk reproducing the very ideology they aim to critique. For example, if an accent identification activity has a set of answers students are instructed to arrive at (e.g., the voice recording A is Singaporean accent) without introducing other examples that do not fall into a “typical” speech style, it is more likely to reinforce the idea of regional standards and stereotypes.

In the pragmatic and critical adoption of the WE framework, therefore, identification and profiling of English varieties should never be the end point. Rather, the boundaries should be introduced in order to be problematized. After learning about a certain variety, for example, students may engage in an activity in which they search online to find speech samples that do not correspond to the characteristics of the variety they learned (e.g., English spoken by Japanese nationals that is phonologically different from typical “Japanese English”). Such a centrifugal use of WE opens the possibility for recognizing the excess of our linguistic practices that incessantly go beyond the confines of the standard. In calling for moving from World Englishes to wayward Englishes, Lee (2017) states:

Encounters with different Englishes, even among people from the same country, are increasingly common, and the sheer heterogeneity of Englishes, even in geographic spaces traditionally understood to be culturally and linguistically homogeneous, means we are losing the ability to determine where someone is from based on their English, and what their English will be like on the basis of where they are from (p. 79).

“The sheer heterogeneity of Englishes” may never be capturable within the boundaries of WE or any other boundaries. Realization of such a theoretical limitation can be an excellent pedagogical moment. Just like a transgressive action is more visible against the background of strict rules, the waywardness of Englishes can be more tangibly encountered in the presence of boundaries. Thus, pragmatic and critical utilization of WE as a pedagogical tool introduces boundaries purposefully in order for them to be traversed. It is through this transgressive use of boundaries, WE remains a useful framework for ELT.

Conclusion

In this chapter, centering the idea of boundaries, we explored the whereabouts of WE today. For this, we first reviewed the historical development of WE and situated it in relation to the neighboring fields like EIL, ELF, and trans-/pluri-/metro-lingualism. This was followed by a discussion of the existing stumbling blocks that continue to impede actualization of pedagogy that is informed by WE and its related fields. The durability of these stumbling blocks demands pedagogical approaches that are both practical and creative. We then showcased some of the WE-informed pedagogies as stepping stones to help bridge existing gaps between WE’s theoretical potential and its pedagogical application. These pedagogical approaches make use of variational boundaries to expose students to diverse ways Englishes are used and to destabilize the idealization of the standard English. Finally, we turned to and examined the critique of WE and argued how theoretical limitations of WE can be rendered pedagogically useful by a pragmatic and critical use of linguistic boundaries. Even though some scholars regard WE as a framework that is “a 20th century construct that has outlived its usefulness” (Bruthiaux, 2003, p. 161), we posit that the pedagogical utility and potentiality of WE have not run out of steam. This is largely because our social, political, and educational systems still rely on modernist institutional conventions. Claiming linguistic rights and recognitions within those systems continues to demand strategic reifications (MacSwan, 2020). Thus, while recognizing the theoretical limitations of WE and the values of a more fluid, mobile, and entangled conception of language, we argue that the very limitations can be utilized for pedagogical purposes. In this way, WE can help to catalyze classroom explorations about linguistic diversity and its related issues, where students and teachers advance their understanding of the reality of English use and users in the globalizing world. Pragmatically and critically, we still use WE.

Reading has a history.

—Robert Darnton, *The Kiss of Lamourette: Reflections in Cultural History*, 1990

History is tangled, messy, contradictory. But is where we are.

—Eamon Duffy, *Faith of Our Fathers: Reflections on Catholic Tradition*, 2006

The question is not how the language arts should be brought together in the learner's mind

but why they should ever be separated.

—Frank Smith, *Reading Like a Writer*, 1983

Introduction

Education is shaped by history, research, and politics, as is true of any domain of intellectual inquiry. In other words, education evolves. It is influenced by academic trends, cultural forces, and individual participants. This is especially true when it comes to identifying the best pedagogy for teaching literacy.

This chapter has two broad aims. First, it describes how the field of literacy education has been framed over the past hundred years or so. This chapter, however, is not an exhaustive anthology of research or researchers in the field of literacy and language development. Rather, it reflects the authors' historical synthesis of multiple threads of research. Second, it foreshadows a shift for the domain of learning, arguing that a biological-evolutionary perspective is needed.

How learning to read and write has been positioned and framed in the past

As American cultural historian [Darnton \(2014\)](#) points out, how we learn to read and write has been shaped by “cultural configurations which have varied enormously over time.” One such cultural configuration is the presence or absence of literate experiences for the majority. Another is the restriction of literacy to certain privileged classes. These influence individual lives as well as society at large in familiar as well as yet undreamed of ways. The justification of these cultural configurations has spilled over into academia and continues to shape our current educational landscape.

Australian literacy educator [Cambourne \(1988\)](#) suggests that those who are unable to access written forms of language, either as readers or writers, experience what he calls “textual alienation”; this essentially leaves them “depowered” in a society that values literacy. He concludes “this textual alienation is a function of how literacy has been taught.”

These core issues reveal that what counts as literacy, and who should have access to it, matters. And these basic parameters have colored how literacy has been researched and discussed in the professional literature for decades. Furthermore, one’s personal, often implicit or unconscious, definition of literacy determines how one approaches the teaching, and hence, the learning of literacy. These differing views of what defines literacy have influenced the relationship between reading and writing through the ages.

Historically—from the cuneiform writing system that appeared in Mesopotamia circa 3200 BC up to our present-day alphabetic system—written language recorded everyday financial transactions, governmental or legal business, or religious dogma ([Dragataki, 2021](#)). As early writing became more specialized and uniform, the profession of scribe emerged. This specialization was highly regarded and a possibility for only the most intellectually able citizens. Similarly, reading was regarded as the domain of a select few and was typically restricted to those in certain professions or from classes of people: elite professionals, wealthy citizens, or the most powerful priests of the time. But since the first uses of written language, reading and writing have always been connected. The earliest scribes’ writing, incisions on pieces of clay, created readers who would simultaneously “decipher them, recognize their meaning, give them voice” ([Manguel, 1996](#)). Just as today, writing requires a reader to bring it to life, whether the recording medium is a clay tablet or digital device.

Historically, however, composition, as we think of writing today, wasn’t encompassed within these early scribes’ definition of writing ([Manguel, 1996](#)). And reading as a critical skill necessary for a healthy, creative society and functioning democracy is also a more recent development ([Dewey, 1916](#)). Academically and culturally throughout time, reading and writing have continued to be thought of as a specialty.

In the late 1800s and early 1900s in English-dominant cultures, the tradition of vigorous, often intense debate began in education about the best pedagogy for teaching reading and writing to the masses. The academic debates typically revolved around one set of either-or questions: Is reading a perceptual skill, through which readers perceive a word in print as one unit? Or is reading about decoding and blending the sounds of the letters in a word?

A historical overview of the different ways of framing reading and writing education

As with all memories, the human brain organizes events as a linear series of episodes ([Tulving, 1983](#)). What follows in this overview is a mostly linear synthesis of two distinct historical schools of thought linking to reading and writing education. It is an attempt to make sense of a complex collection of theories. It should not be regarded as the only truth.

Framing reading and writing education from a psychological viewpoint

In the late 1800s, educators regarded the emerging field of psychology as education’s theoretical home. The alignment between these domains seemed a natural fit because learning was (and still is) considered the purpose of education; it is also a key topic for study in the field of psychology. Psychology regarded learning as “a mental activity” ([Lund, 1927](#)) devoted to “the understanding of mental activity.” An alignment of the fields flourished as educational pedagogy came to be viewed through the lens of psychology. The language (i.e., Discourse) of psychology became the platform educators could use to communicate and/or discuss theoretical issues and concerns about learning, an academic construct that continues today.

In its infancy, the field of psychology sought to apply traditional hypothesis-testing models of research, much like the long-established linked sciences of physics and chemistry. These familiar models emphasized “either-or” experimental research designs ([Tracey and Morrow, 2017](#)), and as psychology sought to be perceived as an established science, it took up this either-or paradigm. The alignment of education and psychology led education to position the early reading debates as an either-or proposition: the Method A vs. Method B dichotomy between look-say and phonics.

Education relied on psychological theories to support both sides of the reading debate. The look-say philosophy in reading instruction intersected with psychology’s Gestalt theory, which argues that people perceive objects as “wholes” ([Kohler, 1929](#)). Another more dominant psychological learning theory of the time, behaviorism, reinforced both look-say and phonics. At the core of psychology’s behaviorism ([Schneider and Morris, 1987](#)) was the belief that learning was basically habit formation; by extension, the reinforcement of correct behaviors and punishment of incorrect behaviors helped ensure that learners developed the right habits. This way of thinking about learning eventually extended to teaching of reading and writing.

An emergence of cultural forces and individual participants

In 1896, American philosopher, psychologist, and educator John Dewey founded the University of Chicago Laboratory Schools, applying and testing his progressive ideas. His views of progressive education (1916) in the United States were a precursor to today’s

constructivism. Dewey's innovative beliefs describing the role of public education in supporting a thriving democracy were revolutionary. His work represented a significant cultural shift in how public education was viewed in American society.

An example of cultural forces influencing the educational field came with World Wars I and II in the 20th century. Recruits numbering in the millions were assessed on their intelligence and other abilities to qualify them for military service and to further establish their fitness for specialized training (DuBois, 1970). Large numbers of military recruits exhibited inadequate literacy abilities, reading in particular. This recognition of low reading abilities was naturally concerning and subsequently filtered down to the school system, continuing to fuel the academic debate between the two dominant methods of teaching reading: look-say and phonics.

Several well-known individual participants played a significant role in this debate. In 1955, American educator Rudolph Flesch wrote *Why Johnny Can't Read—and What You Can Do About It* (Flesch, 1955), taking a strong stance that teaching children to sound out words using rules was the best way to teach reading. The popularity of this book within and beyond the educational world led to the phonics method of reading instruction becoming the predominant method of teaching.

In the 1960s, American educator Jeanne Chall published her groundbreaking book *Learning to Read: The Great Debate* (Chall, 1967). Chall believed that effective reading was contingent upon accurate word recognition, which was best achieved through phonic decoding. She defined the two approaches to teaching reading as code-based (phonics) and meaning-based (look-say). Although Chall used the phrase meaning-based, her definition and usage differed. She used meaning-based to refer to word recognition. Today, the phrase relates to comprehension.

In her research, Chall used concepts, theories, and the discourse of psychology to test which of the two broad approaches to teaching reading, look-say or phonics, was best. After analyzing results from empirical researchers with a variety of test scores and treatments and a reliance on a Method A and B methodology, Chall determined that phonics produced the best results. Chall's research continued a tradition of defining phonics (i.e., decoding to sound) as a basic and hierarchical set of subskills. This belief contributed to a view of reading as a phonics-first process and reinforced a behaviorist orientation in education that is still relevant today.

Implications for pedagogy from the psychological viewpoint

In the decades from the 1890s through the 1970s, writing education was linked to spelling and grammar and very little, if any, attention was paid to composition. The teaching of grammar focused on parts of speech, with students working to identify the right kind of words (e.g., nouns and adjectives, verbs and adverbs) to produce an acceptable text. The relationship between reading and writing was not considered; therefore, reading and writing were taught as separate subjects.

During these decades, comprehension, fluency, and other aspects of reading were regarded as outcomes of accurate phonic decoding. If a reader could decode the words accurately, it was assumed that reader could understand what a text was about.

Because there were two dominant theories of how reading was learned, two instructional methods emerged (Holdaway, 1979). In classroom practice, however, both methods often intertwined and overlapped. Look-say advocates argued children should learn the pattern of the whole word; therefore, instruction consisted of drills using flash cards, often followed up with worksheets. Phonics advocates argued that children should learn to analyze words and their component sounds, hence a reliance on whole class instruction in phonics. This mode of instruction involves identifying letters and corresponding sounds, segmenting and blending sounds in words, and repetitively chanting how words are spelled ("C-A-T spells CAT"), often culminating in the completion of worksheets. In both the look-say and phonics methods, worksheets were used to provide individual, repetitive practice of isolated skills.

The teaching methods that were predominant in this era followed the pattern "teach-practice-test," and they were clearly underpinned by a learning theory that "came straight out of the experimental psychologist's laboratory" (Smith, 1986). Writing instruction was taught separately and consisted of exercises designed to identify correct usage in tandem with grammar, spelling, and punctuation.

If comprehension was addressed at all, it was through questions asked by the teacher and answered by the students after reading a passage together. The teacher's questions were typically about specific details in the passage, reinforcing the idea that comprehension was an outcome of correctly decoding the words.

Assessment during these years was based on the degree to which a student's responses on a worksheet correlated to the questions posed—and whether the answers were deemed correct. The emphasis was on "getting it right." Mistakes were unacceptable and had to be ruthlessly rooted out in case they became "permanently fixed in the child's repertoire" (Cambourne, 1988).

A changing paradigm

Irish historian Eamon Duffy's memorable quote about history being "tangled, messy, contradictory" (2006) seems pertinent when reflecting on the past five decades of research into literacy and language learning. In the previous sections of this chapter, educational research was characterized by an emphasis on the design of experimental psychological research. The next section integrates research on the social aspects of language and literacy learning which promoted the use of naturalistic inquiry. This section synthesizes complex, overlapping lines of research and theory from multiple fields of study.

The emergence of constructivism

The history of constructivism is wide and varied (Tracey and Morrow, 2017). The discussion of constructivism that follows begins with Swiss biologist and psychologist Jean Piaget, “the great pioneer of constructivist theory of knowing” (Glaserfeld, 1990), who, in the early and mid-decades of the 20th century, studied cognitive development in young children. Applying some principles of naturalistic inquiry, Piaget focused on learners and the qualitative development of their understandings. His concepts of assimilation (from which learners respond to new events based on existing schema), and accommodation (whereby learners modify or create schema based on new events) articulated a model of active learning. Piaget also introduced the concept of readiness, by which children progress through stages of intellectual development.

Around the same time as Flesch’s and Chall’s writings, developmental psychologist Lev S. Vygotsky’s seminal text, *Thought and Language* (1962), was translated into English, informing and reshaping Western educational trends. Vygotsky connected speech (both silent inner speech and spoken language) to the development of mental concepts and cognitive awareness; in addition, the connection fueled developmental and educational psychology’s embrace of social constructivism. It also informed his colleague Alexander Luria’s research into the regulatory role of speech (Tupper, 1999). Vygotsky’s theories of language development and cognitive processing described the potential of human cognitive development. Vygotsky gave the field of education, particularly the area of constructivist learning, one of its most enduring and influential concepts: the zone of proximal development. The zone of proximal development is defined as the distance between what a learner can do on his or her own and what can be accomplished with the support and assistance of someone who is more knowledgeable. This concept underpins several contemporary learning theories, including the gradual release of responsibility (Pearson and Gallagher, 1983).

The emergence of a linguistic perspective

Throughout the first half of the 20th century, the dominant theory of learning was based on behavioristic modeling, pulled together into a coherent theory by B. F. Skinner and John Watson (Schneider and Morris, 1987). This theory proposed that the focus of learning research should be on observable behaviors rather than internal emotions and processes; internal processing was thought to be beyond the scope of scientific inquiry. Skinner and his colleagues and followers believed humans acquired language through direct instruction and reinforcement (Skinner, 1957; Winokur, 1976; McLaughlin, 2006). Mid-century, advances in linguistic theory challenged this thinking.

In the 1950s and early 1960s, American psychologist George Miller, the father of the psycholinguistic perspective of learning, linked language and cognition to analyze language creation and use (Miller, 1951). He also pioneered an acceptance of mental processes as proper subject matter for research. Miller’s research on working memory (1956) revealed that the brain is prewired to take in and remember up to “seven plus or minus two” bits of information at a time. This research had implications for both the size and quantity of information bits built into a learning event. His research also brought meaning into the discussion of learning, acknowledging that language is more than just words.

Noam Chomsky, an American researcher who redirected academic trends in linguistics, challenged this behaviorist view in his watershed critique, “A review of B. F. Skinner’s verbal behavior” (1959). In his response to behaviorism, Chomsky challenged the notion that internal cerebral processing could be ignored, leading him to develop his theory to explain the generative nature of all human languages. For speakers to generate sentences they had never heard before, Chomsky insisted humans possessed an innate knowledge of how any language works, a Universal Grammar. Because no learning theory at the time explained how children, who are otherwise cognitively immature, could learn something as complex as language so easily and early, Chomsky argued humans must be born with this innate knowledge. This viewpoint challenged the academic beliefs of linguistics of the time. Although multiple scholars have challenged Chomsky’s view of an innate language-acquisition device (Everett, 2012; Deacon, 1998), Chomsky offered a stark contrast to the thinking that had prevailed (Ellis and Bloch, 2021).

American researcher Ken Goodman (1965, 1967) also challenged the academic trends of the time. His psycholinguistic theory of reading redefined Chall’s term “meaning-based” from word-recognition to a process of continuous construction of meaning by learners. Understandings emerge as readers predict and then confirm or reject those predictions. Goodman defined this as a “psycholinguistic guessing game” (1967). By this, he meant that readers use multiple cues—semantic, syntactic, and graphophonic—to anticipate and hypothesize (i.e., “guess”) as they construct the author’s intent based on information found within the text and within the reader. This thinking was contemporaneous with researchers who argued that language is an integral part of literacy education. The influential researchers who fueled this trend included Rosenblatt (1978), whose transactional theory of reading emphasized the cultural experiences and language that readers bring to reading.

Other researchers in this emerging group included American sociolinguists Labov (1968), Hymes (1972), and Shuy (1976). They proposed the concept of language performance through social interactions; this idea that language has a social component contrasted with Noam Chomsky’s view of linguistic competence. These researchers believed that studying grammar rules does not help learners understand how language is used in the real world, where “meanings may be won by the sweat of the brow, and communication achieved in labor” (Hymes, 1972). Until the 1970s, competence—the internal set of rules that Chomsky’s transformational grammar identified—was considered the only legitimate area of linguistic study. But, by looking at the culture and context in which language is constructed and used, these researchers connected the purpose and production of language while expanding the field in ways that still reverberate. It is also significant that because each of these sociolinguistic researchers had background in anthropology, they applied the canons of anthropological research to the study of linguistic performance. This legitimized the movement toward naturalistic inquiry as a valid research methodology in education.

Extending psycholinguistic perspectives in educational research

By extending his research on the social and cultural dynamic of language development discussed previously, Labov (1972) was instrumental in examining the linguistic features of Black English Vernacular. His groundbreaking research of this form of English, with its various dialects, found it to be as complex as other forms and important for the culture in which it is used.

Contemporaneously with these other researchers, Canadian psycholinguist Smith (1971) introduced the notion of learning as a process. Smith's idea of reading and writing as linked processes contradicted the academic trend of the time, which viewed reading and writing as a set of sequential and hierarchical skills to be acquired by a learner. His theory influenced how educational professionals thought about literacy and also changed how researchers designed educational studies.

British linguist Halliday (1973, 1975, 1978) expanded the idea of language as a social meaning-making process while detailing how language supports various forms of communication. Halliday's research showed that function (the purpose) preceded form (the structure) in language development, challenging Chomsky's notion that form preceded function. In addition, Halliday's ideas about language development emphasized the integrated nature of learning, recognizing we "learn language, learn through language, and learn about language simultaneously" (1979, 1980, 2003).

The process of learning language

Several key researchers continued to study how young children learn the oral version of their native tongue. American psychologists and educators Carroll (1964), Brown (1973), and others explored and wrote about how children learn to talk. By observing children and documenting language development over time for individual children, their research emphasized the social dimension in literacy and language learning. American linguist and educator Carole Chomsky's research of how children learn to control the passive voice further documented how language develops over time, providing support of learning as a process (1969, 1976).

Australian educator Brian Cambourne's Conditions of Learning theory (1988) built on the existing research of native language learning. His naturalistic research explored conditions under which young children learn to talk, producing a grounded theory that explained the physical, social, emotional, and ecological aspects of first-language learning. Cambourne's framework articulated how learning occurs in a natural environment where learning is based on the interactions between a novice and more knowledgeable others with whom the novice has developed strong, bonded relationships. Cambourne proposed these same conditions could be simulated in classrooms to support language and literacy learning.

Continuing to expand the body of research into the social nature of learning, Tomasello (1999, 2003), an American developmental and comparative psychologist and linguist, interpreted social and contextual influences on language for his theory of usage-based linguistics. His social-pragmatic theory proposes that language is developed through interactions with adult speakers. During these exchanges, the child's cognitive skills enable him or her to assess the intentions of the speaker, learn to refine patterns of grammatical use over time. Language, according to Tomasello (2008), is "cognition packaged for purposes of interpersonal communication."

This research into what cognitive scientists and linguists believe is the most complex learning a human ever does had implications for learning in other symbol systems (e.g., writing, art).

Extending the socio-psycholinguistic viewpoint for classroom practice

American educators Harste and Burke (1978) introduced the term "socio-psycholinguistic" to integrate the cognitive work described by psycholinguists Miller and Goodman with the social aspects explored by Labov, Halliday, and other sociolinguist colleagues. Specifically, Harste and Burke studied the ecological contexts in which children learned to understand and respond to symbols. They observed children's initial symbolic behavior in writing, noticing how children used what they saw in their home and cultural environments to make sense of written and spoken language. In particular, Harste's "education as inquiry" (2003) theory proposes that one's ability to learn—including learning to read in all symbol systems—is social in nature.

In her research, a New Zealand developmental psychologist and educator Marie Clay continued a focus on the earliest years of literacy and language learning (1982, 1985, 1991). Her literacy processing theory echoes other socio-psycholinguistic theories. Rather than perceiving children as empty vessels to be filled, Clay's theory values the role that prior knowledge can play in pedagogy, a belief that continues to influence classroom practices in significant ways.

Implications for pedagogy from the linguistic perspective

By the 1970s and '80s, the code-based vs. meaning-based debate had morphed into another dichotomy: direct instruction vs. whole language. Direct instruction (not to be confused with explicit instruction, which means teaching with clarity) is a philosophy and series of teaching methods based on the belief that learning occurs only when the learner is told directly what is to be learned and how to accomplish the learning (Bereiter and Engelmann, 1966). Direct instruction methods of teaching broke content to be learned into hierarchical sequences, with each part being mastered without mistakes. Once the parts were mastered, they were added together to make an overall whole. Whole language proponents believe that learners must be given an opportunity to construct meaning by experiencing demonstrations of language in use. These demonstrations provide an overview of how the component parts of what is being learned fit together as a whole (Goodman, 1986).

Most classroom instruction in the 1970s and beyond reflected a psychological discourse. For example, the ideas of reinforcement being a necessary component of learning—the notion that "practice makes perfect"—and the intent to extinguish errors before they became permanent promoted an objectivist pedagogy. The Initiate-Respond-Evaluate (IRE) pattern of classroom discourse (Cazden, 1988) is a hallmark of this pedagogy. With this method of interaction, a teacher initiates an exchange with students by asking

a question. Students indicate they know the answer by raising a hand. The teacher selects a student to respond. Then the teacher evaluates whether the given answer is right or wrong.

For those who embraced a constructivist perspective through the 1970s and '80s, however, a new discourse emerged. Students were encouraged to collaborate with one another, and texts were viewed as having multiple interpretations rather than a singular (right or wrong) main idea. Terms like "mistakes" and "errors" instead became "approximations" or "miscues"—and "motivation" became "engagement." During this era, reading and writing began to be thought of as a process. For a significant number of practitioners, this change in discourse precipitated a notable shift in the pedagogy for teaching reading and writing.

Where the education profession finds itself today

From the 1980s through the first decade of the 2000s, much theorizing that emphasized a phonics-first approach occurred in educational and psychological circles (Adams, 1990; Lyon and Chhabra, 2004). American psychologist Ehri (1999) and American educators Foorman and Moats (2004) added to the body of research endorsing a skills-based approach to literacy learning. Another American cognitive and developmental psychologist and reading program developer Marilyn Jager Adams summarized the research of the time in the influential book *Beginning to Read: Thinking and Learning About Print* (1990), supporting a phonics-first view of how literacy was taught. These researchers used a psychological, hypothesis-testing paradigm that supported a phonics-first pedagogy to explore cause-effect relationships in learning to read.

Since the dawn of the 21st century, the advancement of technologies such as the MRI has made it possible to explore more deeply how the brain functions during language and literacy experiences. Early brain-to-learning researchers studied MRI scans to determine which parts of the brain are activated during certain activities; this approach resulted in a linear view of how the brain processes and responds to stimuli (Dehaene, 2010; Abadzi, 2016; Castles et al., 2018). Most research of this type continues to use an operational definition which represents reading as decoding of isolated words, rather than define reading as a constructive, meaning-making process.

Recent studies, however, provide a focus on how the brain makes meaning of stimuli it receives (Cobb, 2020a,b; Ellis and Bloch, 2021). When one defines reading as meaning making, rather than simply as decoding print, the type and design of neuroscientific research that can inform pedagogy expands significantly. Researchers, including Hirsh-Pasek et al. (2018), Romeo et al. (2018a,b), and Piazza et al. (2020), have focused on how connections that support language development take shape within the brain. Their findings show language learning to be both socially and contextually situated, reflecting the necessity of interpersonal and interactive experiences for it to occur. Other research concerning reading development details how multiple brain regions and neural pathways that connect and coordinate those regions interact (Kweldju, 2015). Neuroscientists Buzsáki (2019) and Cobb (2020a) conclude that the brain doesn't only represent information but also constructs it.

The distinction as to how reading is defined (i.e., representing information or constructing understanding) and how the brain makes meaning was explored in *Reading—The Grand Illusion: How and Why People Make Sense of Print* (2016), in which American educator Kenneth S. Goodman, American linguist Peter H. Fries, and American neuroscientist Steven L. Strauss write about the remarkable abilities of humans to produce and use language to navigate their world. As quoted earlier in this chapter, Darnton (2014) and Cambourne (1988) believe one's definition of literacy matters. Goodman, Fries, and Strauss, researchers from diverse fields, share this belief. Their research highlights how readers use their eyes, brain, and language to make meaning. It's no surprise that when professionals in different fields collaborate, they build on one another's thinking and break down walls that divide them, thereby exemplifying how meaning is constructed. This collaboration among different disciplines using a meaning-based definition of literacy has implications for moving the field of literacy education forward.

Yet, at the conclusion of this historical overview of literacy in the context of education, debates continue to rage about what distinguishes scientifically-based and evidence-based practice. American educational researcher Gabriel (2018) succinctly captures this state of affairs: "The sloppy, mudslinging nature of these debates has led to confusion, distrust and a tribe-like affiliation with single approaches among practitioners, researchers and policymakers." This present-day cauldron of competing and overlapping philosophies continues to bubble in the background of literacy and language learning. So where do we go from here?

A shift in thinking

Until this point, this chapter has presented a chronological and philosophical tour of the history of the profession. It explained philosophies and dichotomies that have influenced educational practice for the past 50 years. The section that follows explains why a shift in thinking and research about learning to read and write is necessary and why a biological-evolutionary perspective has merits as a path forward.

The psychological experimentation model

The varied psychological and linguistic perspectives that have been applied to reading and writing have existed in silos. The factor that unites many of these disparate theories is their reliance on psychological definitions of learning and psychological interpretations.

What do these psychological connections mean and why does it matter?

In psychological parlance, learning was seen as a “change in behavior” caused by external environmental factors occurring just before any such changes (Lund, 1927). This definition influenced the dominant culture of both psychological and educational research. This culture of both domains was characterized by an emphasis on controlling and testing effects of external factors such as type of motivation, duration of exposure to different external factors, or sequencing of the presentation of material to be learned. This view of learning condoned, promoted, and emphasized establishing cause-effect relationships between whatever factors were being tested.

Why is that problematic? In its earliest manifestations, psychology struggled with its place among the established sciences, including physics, chemistry, and biology. This struggle was caused by ignoring the process through which the hard sciences became credible and trustworthy. That process begins with naturalistic observation to identify and document how phenomena exist and behave in their natural environment. Mini-theories are proposed to explain observations that emerge (Kuhn, 1962; Popper, 1972; Lakatos and Feyerabend, 1999). These mini-theories are then tested in controlled experiments. If a mini-theory doesn’t hold up to scrutiny, it is discarded. Over time, a convergence toward an explanatory, overarching theory occurs that represents the best current thinking but will continue to be tested and evolve. For example, the periodic table in chemistry derived from observations to determine what the basic elements were and how to systematize them. Scientists throughout history engaged in rigorous debate as they proposed, tested, and accepted or rejected ideas and theories. They sought to find patterns to establish consistency, eventually arriving at a widely accepted consensus of understanding. Early psychologists leapfrogged this historical, observational stage. They proceeded directly into experimental design and hypothesis testing without first identifying and describing the way the phenomena they were seeking to understand occurs in an experimenter-free environment (Heft, 2001).

Ultimately, psychology—in its early development as a field of scientific study—didn’t strive to identify and apply their own set of overarching concepts as other scientific domains had. The abundance of extant (often conflicting) learning theories (Culatta and Kearsley, 2021) that have continually emerged from experimental psychology are a result of this leapfrogging. Such a lengthy list of competing theories provides a mute but powerful testament that something is seriously wrong with the way psychology (and therefore education) has conceptualized and researched learning over the last one hundred and twenty or so years.

As American psychologist Harry Heft writes: “Has there been a moment since its formal founding in the late 19th century when experimental psychology was not in a state of theoretical conflict? Select any historical point during its first 120 years and you will find psychologists embroiled in some theoretical squabble” (Heft, 2001). A closer look at the history of psychology shows that a majority of these theoretical squabbles are either directly or indirectly related to the umbrella concept of learning. If that basic overarching concept is so conflicted within education’s chosen theoretical partner, no wonder the derived theories of learning (including learning to read and write) are also in conflict.

If fact, Canadian psychologist Frank Smith claimed in an essay that “education backed the wrong horse when it backed psychology”; he argued that “psychology has never been comfortable with learning” (Smith, 1983). Psychological experiments at the time of Smith’s assertion emphasized the learning and forgetting of 3-letter nonsense syllables rather than assessing learning as a meaning-making process. The belief was that because the nonsense syllables were unknown to the test subjects, the test results could be attributed solely to the variables being tested. Learning to read with meaning and the variables that influence meaning-making were considered to be uncontrollable factors; as such, they were eliminated from the experimental design. Although Smith stated the obvious by signaling these types of experiments were not about learning, they nevertheless informed pedagogy.

Dramatic changes in understandings of the relationship between conceptual metaphors and discourse

In academia, Discourse is a theory which describes the various relationships within a particular setting. It includes the thinking and behavior group members expect others to adopt and use when engaged in the group’s “business.” Conceptual metaphors, or mental representations, are embedded in all discourse (Fauconnier and Turner, 2002; Lakoff, 2004). Conceptual metaphors guide how people think about the world and determine their language and behaviors (Lakoff and Johnson, 2003). As British historian Schaffner (2021) stated: “Metaphors matter. Far from being mere ornamental flourishes that render our speech more vivid, they create important conceptual bridges between fields The imagery we use is never neutral—it reflects deeper cultural assumptions, often about agency and personal responsibility. This has consequences.”

How one defines learning and the research designed to gauge it reflects the metaphor of learning one embraces. Holding tightly to metaphors, and the discourse that arises from their presence, imposes boundaries and can end up “limiting what and how we can think” (Cobb, 2020b). The great debate is a powerful example of how metaphors influence thinking and behavior.

And, for educators who have been immersed in psychological discourse for all their professional lives, another conceptual metaphor influencing their practice is the acquisition metaphor. In this nonconscious metaphor, learning and knowledge are thought of as some kind of reified stuff. And, like other stuff, it can “be measured and weighed as though it has mass, weight, and heft” (Crouch and Cambourne, 2020). It follows that it can also be transferred from one person to another and acquired by someone through a process of moving the stuff from one place (e.g., an expert’s mind) to another by an act of transmission (using language as the medium). It can be discussed, communicated, and thought about as the static end product of an act of learning (e.g., comprehension is seen as something that occurs after one reads rather than as a process of meaning-making).

Viewing the end product of learning as knowledge continually reinforces this underlying acquisition metaphor, one in which learning and knowledge is seen as stuff and teaching as the delivery of this stuff. For example, a teacher’s language that labels responses as right or wrong is an indicator of the heft of the ideas; signaling to “get this information into your head” reinforces

the metaphor of learning as something transmitted. Australian educator [Cambourne \(2015\)](#) identified this language and associated behaviors as the Discourse of Acquisition and argued it is the dominant discourse in education and psychology today.

An alternative to this view of learning is the Discourse of Meaning-Making ([Langer, 2011](#); [Cambourne, 2016](#)). Instead of a discourse that subconsciously implies that learning is stuff to be transmitted, a Discourse of Meaning-Making frames learning as a process of using linguistic and other symbols to engage in continuous cycles of constructing, deconstructing, and reconstructing these meanings through interactions with others. In other words, meaning is constructed using whatever medium is available to us—print, graphic, oral, signing, gestures, etc.—as we communicate with and think alongside other learners. This need to communicate is both innate and generative. Meanings are continually being adjusted and updated as we learn more. In a Discourse of Meaning-Making, learning is characterized by, rather than defined as, an ever-changing, dynamic mix of knowledge, understandings, feelings, values, and skills linking to what is being learned. In addition, a Discourse of Meaning-Making embodies an intrinsic dynamic that ensures we learn to exchange and refine meanings with others using symbols.

While parsing these different discourses may seem a trivial exercise in semantics to some, the ramifications are compelling. This reconceptualizing of learning forces a significant shift in thinking about learning, with implications for both research and pedagogy. This innate need to communicate with others using symbols positions learners as active and agentive in the learning process. The ability to use symbols combined with an innate need to communicate using those symbols are two linked human characteristics, unique to the species ([Deacon, 1998](#); [Fauconnier and Turner, 2002](#); [Tomasello, 2003](#)). Through the ages, all cultures have struggled to come up with the best way to learn this symbolic behavior. And this cultural issue is a distinctly human challenge.

Going forward: embracing a biological-evolutionary perspective

For the past century, the social sciences—especially psychology, education, and other cognate domains—have been grappling with this human challenge of learning to read and write. Interpreting this issue from a psychological perspective has hindered the ability to identify or agree on a definitive theory of learning to read and write. Biomimicry, a relatively new branch of biological-evolutionary science, represents an alternative approach, one that focuses on the science and art of emulating nature’s best biological ideas to solve human problems ([Biomimicry Institute, 2021](#), <https://biomimicry.org/>). This stance offers social scientists a fresh perspective for exploring literacy and language learning.

Biomimicry ([Benyus, 1997](#)) relies on two fundamental principles. First, evolution has already solved many of the human challenges with which science is currently grappling. Second, advocates of biomimicry insist that, to solve a human problem, it must be interpreted from a biological or natural perspective. “Biomimicry asks us to learn from and then emulate the intelligence embedded in 3.8 billion years of learning, using nature’s forms, processes, and ecosystems to create more sustainable designs” ([Fig. 1](#)) ([Biomimicry Institute](#), as cited in [Crouch and Cambourne, 2020](#)).

So how does biomimicry connect to educational theory?

At the core of biomimicry is the belief that its principles should be applied only to issues that are important for human survival. Being literate is both important to, and significant for, our survival as a species for two reasons. First, being literate is necessary for maintaining democracy as we know it. A healthy, creative society and a functioning democracy require critical thinkers and critical analysts. Given the relationship between literacy and democracy, it is imperative for schools to produce graduates who are highly effective readers and writers. Second, literacy is significant for human survival because of the vital need to address and resolve the dominant global ecological, social, economic, scientific, ethical, and moral issues related to sustaining our species on a planet that has finite resources. It follows that regular cohorts of highly literate graduates are essential for creating an ongoing international supply of talented researchers, theory builders, thinkers, problem finders, and problem solvers—and especially well-equipped

Among the multitude of designs that have evolved in nature through the ages is the pervasive ecosystem of termite mounds. Termites in the Northern Territory of Australia must keep their eggs within a certain range in the very hot climate. Over billions of years, these insects have worked out how to design their six-foot mounds to survive in the hostile conditions. By incorporating strategically placed openings and internal structures, the termites maintain temperatures that ensure their survival. Engineers have studied the termite mounds and applied similar elements of climate control in designs for human structures. This is just one example of many human quandaries that have been addressed by applying principles of biomimicry.

Fig. 1 An example of biomimicry in action.

teachers—across all domains of knowledge and expertise. Solving this challenge becomes even more urgent because of the exponential rate at which information is increasing and the skills required of readers and writers who must quickly assess the truth-value of the textual messages that bombard them.

How is literacy and language learning viewed from a biological-evolutionary perspective?

Psychological discourse tends to define and frame learning as a change in an animate organism's behavior "caused" by contiguously occurring external factors and events. Biological discourse, however, is radically different. Biological-Evolutionary discourse frames human learning as a unique form of learning, one that is available only to our species (Deacon, 1998; Iacoboni et al., 1999; Fuster et al., 2000; Donald, 2001; Ramachandran, 2004; Feldman, 2008; Tomasello, 1999, 2003, 2008). Framing human learning this way triggers the question: Why is this kind of learning and knowing so unique for our species? Addressing this question has far-reaching implications for resolving the human challenge of learning to read and write.

Evolutionary biologists argue learning and knowing using symbols is ultimately what distinguishes *Homo sapiens* from all other forms of life on Earth. Through the long process of evolution, learning and knowing symbols came to define our species; therefore, it must be a form of species-survival behavior (Fauconnier and Turner, 2002). And not only has learning and knowing using symbols made us the dominant species on the planet, but the fact that this dominance has not resulted from superior physical strength, speed, size, teeth, or claws further strengthens the argument that this ability is vital for the survival of our species.

In addition, the selection of this ability to use symbols provides our species with two unique, species-specific, cognitive capabilities. First, it allows us to create complex knowledge (or meanings) using abstract symbol systems. Without this ability, we would not have mathematics or science or poetry, for example. Second, we can apply this knowledge (or these meanings) to the everyday challenges of the survival of our species. Not only are we the only species of living organism on the planet that can construct abstract meaning using a diverse range of symbol systems, but we can also store these meanings in memory, revisit them, manipulate them, extend them, refine them, and build on them. As a consequence of these processes, we can share and communicate what we've constructed with other members of the species to solve problems, whether they involve mundane challenges or world-changing issues.

This evolutionary selection of making meaning using abstract symbols is supported by much research (Deacon, 1998; Iacoboni et al., 1999; Fuster et al., 2000; Donald, 2001; Ramachandran, 2004; Feldman, 2008; Tomasello, 1999, 2003, 2008) culminating in the same conclusion: Until our ancestors developed this way of using abstract symbols, communicating in this way to identify and solve issues of survival was a new, untried form of cognition. As American cognitive scientists and linguists Fauconnier and Turner (2002) note: "That every human being can do it, but no member of any other species can do it should tip us off immediately to the evolutionary development that was needed to make such feats possible. Only really big brains connected in special ways, and doing a lot of work as trained by the cultures, can even begin to handle these feats."

Further support for the aforementioned conclusions can be found in archeological and evolutionary records that show this previously untried form of cognition created and unleashed new forms of knowing, learning, thinking, and communicating. This not only made humans unique among all other forms of life, but has had profound impact on the planet, including in some possibly irreversible ways (Deacon, 1998; Iacoboni et al., 1999; Fuster et al., 2000; Donald, 2001; Ramachandran, 2004; Feldman, 2008; Tomasello, 1999, 2003, 2008). The ability to construct and communicate abstract meanings using symbols offered our biological ancestors a unique and powerful tool for survival in a hostile environment (Deacon, 1998; Donald, 2001). It follows that our descendants will need these same tools to address and resolve the multitudinous global ecological, social, economic, scientific, ethical, and moral issues they face.

Fauconnier and Turner (2002) summarize the process of developing this system of constructing and communicating messages this way:

Two million years ago, australopithecines, equipped with nonlinguistic ape-like mental abilities, struggled to assemble by fits and starts, an extremely crude symbolic system—fragile, difficult to learn, inefficient, slow, inflexible, and tied to ritual representation of social contracts like marriage. We would not have recognized it as language. But language then improved by two means. First, invented linguistic forms were subjected to a long process of selection. Generation after generation, the newborn brain deflected linguistic inventions it found uncongenial. The guessing abilities and intricate nonlinguistic biases of the newborn brain acted as filters on the products of linguistic invention. Today's languages are systems of linguistic forms that have survived. *The child's mind does not embody innate language structures. Rather the language has come to embody the predispositions of the child's mind* [emphasis added]

How does this shift in perspective help resolve our human challenge of learning to read and write?

The idea of language being structured by the human mind to communicate meanings with others—rather than the mind being structured by language imposed on it—is a seismic shift in cognitive science. If meaning is present for a learner, the learner will attempt to construct a form of language to express and communicate it to others. However, this language may differ from the language used in the classroom. This implies a meaning-centered pedagogy which honors children's first responses as approximations of the Discourse of Meaning-Making is fundamental for effectively teaching students to read and write. This perspective on pedagogy echoes observations from linguist Halliday (1979/1980; 2003), who said we "learn language, learn through language, and learn about language *simultaneously*" [emphasis added].

In alignment with Halliday, Biological-Evolutionary perspective equates the term “learning” and its cognates (e.g., “knowledge,” “understanding,” “comprehension,” “knowledge building”) with “meaning” and “meaning making”. Rather than use psychology’s “change in behavior” definition, a biological-evolutionary perspective explains learning as a process of making meaning using symbols. Meaning is “an unpredictable mix of personally constructed internal pictures, sounds, and feelings, which seem to be unleashed by, and closely related to, the range of symbol systems humans are constantly using and manipulating to create new topical and contextually relevant meanings that allow them make sense of the world” (Cambourne, 2015). This internal cognitive construction of the human mind helps us make sense of the world and makes communication with others possible; both are essential for the survival of the individual and the species. Biological and cultural evolution has selected the construction of meaning using this range of symbol systems as a species-survival trait for *Homo sapiens*. This is a radically different way of thinking about learning as *meanings constructed by the learner, not something done to a learner*.

Furthermore, the ability to control the dominant symbol system, the oral form of language, has been so successful as a species-survival mechanism that evolution has ensured that young members of the culture develop this ability in ways as fail-safe as possible. The principle of Occam’s razor, or “evolutionary parsimony” (Dawkins, 2004), states that the best scientific principle to explain complex issues is the simplest one. So, when applying this principle to biological-evolutionary theory, the same conditions for learning the oral form of language should also support learning to control the other symbol systems a culture values and uses, including the written form of language (i.e., reading and writing). Thus, the ecological, social, physical, and emotional conditions that support learning to talk provide a scientifically rigorous framework for a pedagogy that supports learning to read and write (Carroll, 1964; Cambourne, 1988; Brown, 1973; Tomasello, 1999, 2003, 2008).

Final thoughts on the future of educational research

In the future, to design credible and trustworthy research, educators should consider a biological-evolutionary perspective as a framework for research and pedagogy. A summary of key principles to guide educators includes:

- a focus on research that explains how systems work, rather than research that seeks to prove cause-effect relationships
- honoring the centrality of meaning-making in the processes of literacy and other learning
- respecting the natural and cultural conditions under which learning occurs in classrooms and beyond

As this chapter has detailed, our history of research in literacy development and implications for classroom instruction has been messy and complicated; nonetheless, biological-evolutionary theory has clarified the social, cultural, and physical factors that support the basis of scientifically derived learning-to-read-and-write pedagogy. This theory confronts the culturally determined disempowerment of learners through “textual alienation” referenced at the beginning of this chapter (Cambourne, 1988). With this new discourse based on biological-evolutionary theory, teaching decisions can fully support and promote learning as a meaning-making process using symbols. Simplifying the process of producing critical readers, writers, and thinkers may help ensure that democracy as we know it has a chance of surviving.

Introduction

L. S. Vygotsky’s essay on the *Prehistory of Written Language* (1931/1997) highlights four primary features of children’s early writing development which can also be considered fundamental to developmental science principles (cf. Gottlieb, 2003a,b; Granott and Parziale, 2002; Overton and Molenaar, 2015; Siegler and Crowley, 1991; Valsiner and Connolly, 2003; van Geert, 2017):

The history of the development of written language of the child presents great difficulties for research. To the extent that this can be judged by extant materials, the development of written language does not proceed along a single line preserving a continuity of forms. The history of the development of written language contains the most unexpected metamorphoses. We frequently encounter characteristics of spasmodic changes or breaks in the line of development. The line of development of written language in the child sometimes stops almost completely, then suddenly, as if completely out of nowhere, from outside, a new line begins and at first glance it seems that between the broken off past and the beginning new, there is absolutely no continuous connection. But only a naïve representation of development as a purely evolutionary process accomplished exclusively by gradual accumulation of separate small changes ... can conceal from our eyes the true essence of the processes that are occurring. Only someone who is inclined to imagine all the processes of development as processes of germination will deny that the history of written language in the child is fully entitled to be represented by a single line of development regardless of the breaks, dying off, and metamorphoses.

Vygotsky (1931/1997, p. 132).

Principles of development

From Vygotsky’s statement as well as from other findings within the literature of developmental science (cf. Fischer et al., 2003; Gottlieb, 2003a,b; Gottlieb et al., 2006; Overton, 2015; Valsiner and Connolly, 2003; van Geert, 2003, 2017) the following principles can be identified: Namely, *that normal growth is characterized by spurts, plateaus, and regressions, rather than gradual growth*—in other words—*development typically is not smoothly uniform and cumulative, but asynchronous and nonlinear*. As Thelen and colleagues (Thelen and Corbetta, 2002; Thelen and Smith, 1994) have pointed out in their studies of the development of infants’ early motor systems, even related subsystems involved in babies’ early kicking, walking and reaching behavior do not develop at the same pace—each subsystem seems to have its own timetable for development and ongoing coordination between all of the subsystems is dynamically driven by both internal as well as environmental factors.

Secondly, however, *increased variation often occurs after long periods of stability*. This characteristic of the development of many species is one of the fulcrum points of the theory of “punctuated equilibrium” developed by the late paleontologist, Stephen J. Gould (2002), and his colleague, Niles Eldredge, as a modification of evolutionary theory. However, similar trends in the history of scientific thought have been noted by Piaget and Garcia in their book *Psychogenesis and the History of Science* (1989). Nonetheless, similar to other revolutionary ideas in science (see Horwich, 2010; Kuhn, 1962, 2000), long-believed, well-entrenched theories are

difficult to dislodge. For example, despite empirical data to the contrary available over several 100 years, Aristotle’s ideas regarding motion survived over a millennium before seriously being questioned in physics (Piaget and García, 1989).

Thirdly, *what seems to be a phenotypic discontinuity in development is often reflective of the deeper continuity of the developmental trajectory*. Or rather, what seems to be an “absence” at times of visible development in an area, does not imply the “nonexistence” of the skill or ability in question—the latter may simply be obeying a deeper law of development in which some other level of related reorganization is taking place prior to more rapid and mature development.

The prior principle discussed above then leads to a last observation of development that *wide variation within any level of development at any one point is the rule rather than the exception*. For example, Siegler (1995) has persuasively shown that even when elementary children know a more sophisticated method for calculating mathematical sums, they will still employ lower level processes (such as counting on their fingers, or orally counting all the numbers in the equation) at least as often as the more advanced method. Similarly, Fischer and Yan (2002) have shown in an analysis of Darwin’s journals written while aboard the *Beagle* that Darwin simultaneously held many levels of beliefs about the processes of evolution both prior to and during his writing of the *Origin of the Species* (1859/2003).

It appears, then, that both children and adults at any level of development have at their command a range of abilities which they employ sometimes economically—and sometimes not—to solve a variety of problems. What *doesn’t* seem to be the case, however, under any circumstances, is that development involves the simple acquisition of a more advanced behavior or level of knowledge which then automatically becomes the normative way of operating. Rather, children and adults only “slowly abandon” old strategies which do not serve them well in the process of experimenting with newer learning strategies. Siegler (1996) has characterized this simultaneous orchestration of ability in his description of “overlapping waves theory” where, at any one time, as he has shown in mathematics learning (Siegler, 1995), and we (Yaden and Tardibuono, 2004, 2011) will illustrate for early writing later in this paper, children have several strategies at hand from which they draw in devising solutions for a variety of numerical and literacy tasks.

Development is complex and nonlinear

Another statement by Vygotsky (1931/1997) expresses the complexity involved in, particularly, child development:

But a positive picture [of child development] is possible only if we radically change our representation of child development and take into account that it is a complex dialectical process that is characterized by complex periodicity, disproportion in the development of separate functions, metamorphoses or qualitative transformation of certain forms into others, a complex merging of the process of evolution and involution, a complex crossing of external and internal factors, a complex process of overcoming difficulties and adapting (p. 99).

Vygotsky used a *geological* metaphor to characterize the above process—just as the strata of the earth is compressed, fractured and riven with heat, pressure, water and the untidy accumulation of extinct lifeforms, so are the influences of development comingled, merged, piled up and transformed. Thus, anyone who has worked closely with young children can appreciate Vygotsky’s comments particularly regarding the discontinuities, breaks, dying off, commingling and metamorphoses of which he speaks regarding children’s growth toward mastery of the written language system.

A retrospective lens on interpreting developmental discontinuities in early reading and writing

Even for researchers who have spent a majority of their professional lives studying early reading and writing behaviors, a writing sample like the one produced by 5-year-old Anthony, an emergent Spanish/English bilingual, still provokes wonder and amazement at the way a few graphic symbols can be arranged in such a dazzling display of directional exploration, combinatorial creativity, and topological range to represent both words and names, including his own (Fig. 1).

But what types of early literacy models (cf. Hanno et al., 2020; Tracey and Morrow, 2017) are there currently which can explain, in any systematic way, the range of writing performances by young emergent bilinguals (cf. Yaden et al., 2019) like Anthony’s with the obvious visual discontinuities and departures from the conventional standard? What types of models, metaphorical, statistical or otherwise (cf. Alvermann et al., 2019; Reichle, 2021; Tracey and Morrow, 2017) does the field have which can provide an explanation, for example, for how *each* graphic string represented in the sample shown is illustrative of an important feature of a unitary developmental trajectory? Or how do all of the graphic strings together speak to the typical or, perhaps, atypical trajectory being built at this moment in time?

For reasons which will be discussed shortly, the type of model needed to illuminate developmental growth is *not* what is pictured in Fig. 2 despite that model’s popularity as a model of early literacy development.

The type of model illustrated in Fig. 2 is characteristically called “Simple” (see Gough and Tunmer, 1986; Hoover and Tunmer, 2018; Petscher et al., 2020; Seidenberg, 2017) as it is based upon the equation “Decoding (D) × Language Comprehension (LC) = Reading Comprehension (RC)”. Nonetheless, Paul van Geert (2003) has also described such a model as “retrospective”—in other

Fig. 1 Anthony's writing sample at 5-years-of-age.

words, “one that looks at the developmental processes from the perspective of a static end state and views all preceding states in light of this end state” (p. 641).

In addition, as Paris (2005) has pointed out related to the modeling of early literacy skills, researchers seldom take into consideration *either* the different developmental time scales of the variables which are measured *or* the fact that strong correlations depend upon only the *partial development* of abilities—given that only partial development ensures statistical variation.

One interpretation which can be drawn from Paris' observations is that “constrained skills” or those abilities which seem to develop faster or early—such as name writing—fall out of the model quickly since most name writing scoring systems that index figural aspects reach ceiling scores very rapidly as most children learn to write their names prior to kindergarten in many cases. On the other hand, elementary outside-in skills (see Whitehurst and Lonigan, 2002) such as language development, vocabulary knowledge, conceptual and domain knowledge—which are learned across the lifespan and are harder to measure—drop out of the model later either because of wide variation within the groups being measured or minimum variation due to test difficulty.

But whether or not the variables measured statistically fall out early or late, we are faced with the decision, as Paris (2005) reminds us, of interpreting the findings of developmental “discontinuities,” at least according to the Simple Model of Reading (Gough and Tunmer, 1986), which relies upon the lack of path coefficients in the model below (see Fig. 2), as supporting the following:

1. That elementary “outside-in” knowledge (as vocabulary or concept growth) doesn't correlate with reading in grades 1 or 2,
2. That vocabulary growth becomes less important after preschool and kindergarten, and,
3. That learning how to write one's name completely captures what it means to be an early writer.

Thus, we must interpret these discontinuities as *either* being theoretically robust according to the model or, on the other hand, as *artifacts* of factors relating to both statistical conclusion validity of the measures used and of inadequate theorizing of the reading/writing acquisition processes, treating the various aspects of literacy growth as developmentally isomorphic across time—which clearly they are not.

Toward a dynamic, “historical” modeling of early literacy: from being to becoming

Thus, there are at least two reasons to be highly skeptical of “retrospective” accounts of literacy development. First, according to Siegler (2006),

Knowledge states are easier to describe than change processes ... and the prolonged emphasis on documenting static states results in a distorted description of development, one in which children appear to spend far more time *being* than *becoming*.

While retrospective or static state models may be important for sketching out possible relationships between constructs or variables, they do not actually measure change processes themselves, but rather static states of knowledge separated by arbitrary time

Fig. 2 A structural model of the development of inside-out and outside-in skills from pre-K through 2nd grade. From Whitehurst, G., Lonigan, C., 2002. Emergent literacy: development from prereaders to readers. In: S. B. Neuman, S.B., D. K. Dickinson, D.K. (Eds.), *Handbook of Early Literacy Research*. Guilford, New York, NY, pp. 11–29.

periods. And as [Vygotsky \(1931/1997\)](#) pointed out, it is only when the *becoming* is studied from a “historical” perspective that the richness of development shows itself.

To study something historically means to study it in motion. Precisely, this is the basic requirement of the dialectical method. To encompass in research the process of development of something in all its phases and changes—from the moment of its appearance to its death—means to reveal its nature, to know its essence, for only in movement does a body exhibit what it is.

Secondly, according to [Vygotsky \(1934/1987\)](#) and other developmentalists ([Bronfenbrenner, 1979](#); [Edelman, 1992](#); [Tomasello, 2019](#); [van der Veer and Valsiner, 1991](#); [Waddington, 1957](#)) knowledge and abilities which develop first or early do not simply fade away, but rather are incorporated into the fabric of more advanced growth and undergo change themselves on the “trailing edge” of growth, as it were, even as newer advanced concepts are added to the leading edge. Thus, as Vygotsky noted again, “The new higher concepts, in turn, transform the meaning of the lower. The adolescent who has mastered algebraic concepts has gained an advantage from which he sees the concepts of arithmetic in a broader perspective” ([Vygotsky, 1934/1987](#), p. 202). Therefore, higher order concepts illuminate and bring a broadened perspective to formerly held understandings, thus effectively transforming the entire

learning and developmental system throughout, making it even more efficient, or in Piaget’s (1977) words, a dynamic system always advancing and seeking an “optimizing equilibration.”

And we would submit that as a child embarks upon the journey of becoming a literacy learner and a user of such symbols as we associate with that learning—a journey which continues over decades—that what is learned along the way does not become less important after its initial appearance, but rather undergoes continual reorganization within the learner’s socio-emotional and cognitive networks in ways which enrich the whole learning system—making the child, adolescent and adult even more efficient in acquiring more complex forms of knowledge, in other words, nothing is wasted, nothing is lost.

Learning to write in Spanish—managing multiple perspectives

We want to now turn to some specific examples of children writing their names as well as other words to illustrate the range of variation in understanding that children exhibit during such tasks, variation which is difficult, if not impossible to demonstrate in a retrospective model such as in Fig. 2.

Depicted in the next few Figures (nos. 3–8) are several 4–5-year-old, Spanish-speaking children’s writing performances across 11 tasks (cf. Ferreiro and Teberosky, 1982) as they wrote their name, their mother’s and father’s names, several words *mama*, *papa*, *nene* (*baby*), *oso* (*bear*), *sapo* (*toad*), *mapa* (*map*), *pato* (*duck*) and a sentence—*mi nene toma sol*—*my little girl sits in the sun*.

After each word was written, the child was asked to read it back, pointing with their finger, and, in the case of the child’s name, the first and last few letters were covered, and the child was asked to read what symbols were uncovered.

In the actual testing protocol with the child, each word was written with a different marker so that it was easier to tell which string was which, although in a few cases, the child’s personal preference for certain colors overrode the researchers’ instructions.

The following are just a few examples from a corpus of 500 or so writing samples which were collected over 2 years in a study (Tardibuono, 2006; Yaden and Tardibuono, 2004, 2011) funded by the Center for the Improvement of Early Reading Achievement (CIERA). Note the differences, particularly, between how the children write their names and the other words.

As can be seen in Figs. 3–8, the children wrote using mostly a combination of uppercase letters and letter-like symbols, having a range of 3–11 symbols per word which they rearranged in different combinations when writing different words. While some were more particular about writing the words in a column, others wrote simply where there was space to write with some children (not shown here) taking as many as three pages to record all of the words. Despite the variation in how the children chose to represent each one of these words, one of the more obvious features of the samples is that the child’s name is the one word which is conventionally written. And, indeed, these examples illustrate, as many (e.g., Bloodgood, 1999; Cabell et al., 2009; Levin et al., 2005) have pointed out over the years, of the importance of the child’s name in the beginning repertoire of what they feel that they can write—at least in a situation where they are requested to write.

Fig. 3 Writing samples from 5-year-old Andres. From top left: Andres’ name, Martha (mother’s name), Alphonso (father’s name), *mama* (written vertically as “map”).

Fig. 4 Writing samples from 5-year-old Andres. From top left: oso, mapa (bp), papa (AD), pato (AE), nene (if), mi nene toma sol (PO), sapa (sp). **Figs. 3–8** from Tardibuono, J., 2006. A Psychogenetic Analysis of Spanish-Speaking Preschoolers' Emergent Writing: A Developmental Trajectory Toward the Phonetization of Speech (Publication No. 3238342). Doctoral Dissertation, University of Southern California.

Fig. 5 Bernardo's writing sample.

Fig. 6 Jason's writing sample.

Fig. 7 Jeanette's writing sample.

Fig. 8 Maria's writing sample.

However, in the samples illustrated, only Andres (Figs. 3 and 4), according to all that we could detect from the testing situation, understood that the symbols being written in his name and other words (e.g., mama, papa, nene, etc.) were “second-order” in that they represented smaller, linguistic segments of the name (phonemic) or word (syllabic) as it was spoken. In all the other cases, covering up portions of the child’s name resulted in the child either not being able to recognize it or changing the form to another name with which they were familiar.

Thus, for a majority of the children, the name was treated as a “logo” of sorts (cf. Tardibuono, 2006), in other words, a graphic which needed to be taken as a whole in order to be meaningful or, in Vygotsky’s terms (1931/1997), a “first-order” symbol referring directly to their identity as a person. It is also an example of what Luria (1988) described as illustrative of the “glass window theory,” indicating that children and adults too, in some cases, “look through” the form of a language directly to the meaning.

In addition, we discovered that while Andres (Figs. 3 and 4) understood that his name could be “sounded out” phonemically, this understanding did not extend to his mother’s or father’s name which were understood as intact graphic strings as was the word “oso” which he had been able to write conventionally several months earlier.

Further, while he demonstrated a clear understanding of what Ferreiro and Teberosky (1982) have termed the “syllabic principle”—that most of the two-syllable words he was asked to write needed one symbol per syllable—any individual symbol might represent a variety of sound units. In addition, he also wrote the entire sentence “my little girl sits in the sun” with two symbols as well—“PO” (see Fig. 4)—segmenting the sentence into larger clausal chunks as well as changing the meaning of the sentence to something more relevant to him, i.e., “my mother [P]... points at the sun [O].”

From what we could tell from this assessment and others we did in the classroom, Andres represented nearly the entire range of the five levels which Ferreiro and Teberosky (1982) have described—from a very global syncretism, to understanding the syllabic principle, and even to demonstrating phonemic awareness—all in the span of the 10 min it took to produce the writing sample. The point we want to underscore here is that Andres’ range of understanding of the structure and symbolic aspects of the written system cannot be adequately determined by only looking at the figural representation of his name. In fact, Andres would actually be scored lower, using some of the more common assessments of name writing such as Hildreth’s (1936) or the *Phonological Awareness Literacy Screening* (PALS) scoring system (Invernizzi et al., 2004) because of the two letter reversals, even though none of the other children who wrote their names conventionally could segment them into linguistic units.

The importance of showing variation in modeling literacy behavior

Thus, we would like to assert that name writing—in and of itself—is not completely informative of what a child is learning about written language as are other types of writing tasks the child might attempt. What can be seen from the writing samples is that children’s early writing performances are *highly varied* both between children as well as within any one child’s specific performance. A child’s accomplishment of a series of writing tasks such as ones comprising the research protocol illustrated is not seamless, but interspersed with interruptions of various sorts, hesitations, perplexities as well as certainties about how some words are to be written (cf. Rowe, 2015).

Computational vs. observation models of literacy development

If our analyses of very young children’s writing is limited to only what we see in their names, then we have hardly scratched the surface in understanding their developmental trajectory toward becoming facile with the written system. Notwithstanding the tremendous accomplishment of writing one’s name at 3- or 4-years of age, most of the intellectual effort of which is invisible in the brief moments of the act, at this period in a child’s growth, it is a “situational” performance—requiring knowledge which may or may not extend to writing other names or words even a few seconds later. Therefore, name writing must be considered within a larger context of writing tasks and purposes within the network of a child’s wider understanding of the use of written symbols before any display can be usefully interpreted.

The type of developmental complexity we have just witnessed cannot be represented in the model above (see Fig. 2). Relying on the *computation* rather than on the *observation* of change, the above depictions are “naïve,” as Vygotsky (1931/1997) stated, in the sense that, first of all, discontinuity—or nonlinear relationships between states—is assumed to be indicative of an absence or the waning of a relationship.

Secondly, as Bronfenbrenner (1977, 2005) has pointed out, standardized regression weights are a “one size fits all” computation, assuming that the trajectory of development is uniform over each individual. As we have seen (with Andres), this uniformity doesn’t even exist within individuals for many variables measured. Further, the point that all participants in an experimental group or in a randomized clinical trial *don’t* benefit from the intervention is strikingly apparent in a recent update of the Perry Preschool Study entitled *Lifetime effects: The high/scope Perry Preschool study through age 40* (Schweinhart et al., 2005) where 8 case studies are reported. Interestingly, the individual having the highest number of “success” indicators (education, employment, criminal record, and family/community life) is actually a *no-program* female—in other words, one of the control group members. Heckman (2005), a Nobel Laureate in economics, although praising the study for its many strengths, states the following:

Comparisons in this monograph are made cross-sectionally at ages 27 and 40 without analyzing the individual life cycle profiles that would be of interest for understanding human development processes. ... It would be valuable in a continuation of this study to analyze individual growth profiles rather than group means over time (p. 230).

Heckman goes on to suggest that there are several ways to be more precise, statistically, about the individual trajectories in this study which could include small sample parametric tests, event history and sensitivity analyses.

In a similar vein, but through an anthropological and sociological lens, Diana Slaughter-Defoe, also commenting upon the Perry Study, makes the following observation:

It seems that after the preschool program ended, even the program participants had evidence of serious life challenges in the form of continuing poverty, exposure to drugs in the communities in which they lived, and the multiple family and social problems that can spiral out of control without help. I wish it had been possible to ascertain how their obvious resiliencies enabled them to overcome those challenges.

Slaughter-Defoe (2005, p. 238).

The point that both of these scholars touch upon is the absence of any developmental information about just how did the preschool experience link with, as Slaughter-Defoe suggests, “the multiple family and social problems that can spiral out of control without help.” Thus, without a strong developmental and theoretical understanding of just how the early experiences linked with later ones, we are left with an unspecified, unknown alternative theory of effects that explains how a non-program participant, similar in initial conditions, but without the benefit of an intensive early childhood program, can still end up after nearly four decades as the highest achiever.

Models of multidimensionality

While methodologically it is important to do more sophisticated quantitative and qualitative research, it is perhaps more important for those of us studying the trajectory of literacy growth over time to have a more nuanced and powerful theory to explain how human beings develop (cf. Tomasello, 2019; Yaden et al., 2014).

So then, what types of models and developmental principles are suggestive in explaining complex patterns of behavior such as we see in young children learning how to write?

For some physicists, mathematicians and chemists at the [Institute of Figuring \(n.d.\)](#) in Los Angeles, these crocheted objects (Figs. 9 and 10), knitted by these same researchers, are physical models of not only of concepts in hyperbolic geometry, but also of natural shapes in the universe. It is also suggested by the group of scientists who crochet these shapes that the various curves and involutions may represent lines of development of different types of physical or conceptual development.

While we are limited in our ability to understand much beyond two dimensions, particularly in our methods of assessment, statistics and research design, we operate in the real world in a least as many dimensions as we have senses—and then some—from our personal experiences, ethnic backgrounds, family histories, school experiences, habits of thinking, and belief systems.

Thus, each one of the convolutions and involutions pictured could be seen as representing one facet of learning which is distinct in some ways, but ultimately connected to the whole system. It may very well be that these shapes are also a fairly accurate image of what children go through in learning a complex skill such as learning to read or write.

Suppose we hypothesize that each curvature in the hyperbolic plane of Fig. 11 represents a child’s growing ability to understand and eventually control the multiple aspects of the task we call learning to write. At any one time, these contours and cleavages may appear to operate somewhat in isolation, but as can be seen, they are nonetheless connected with one another in a complex, but unitary shape, as Vygotsky observed nearly a century ago.

Prospective, developmental models of learning

In contrast to retrospective theories of development, “prospective” theories such as represented by *dynamic skill theory* (Fischer and Biddell, 1998; Fischer et al., 2003), *indeterministic constraints modeling* (Valsiner, 1998), *probabilistic epigenesis* (Gottlieb, 2003a,b), and *Bronfenbrenner’s bioecological theory of human development* (Bronfenbrenner and Morris, 1998, 2007) are theoretical approaches in child and developmental psychology underscoring the “normal” processes of learning as being among other things,

(a) Characterized by spurts, plateaus, and drops rather than gradual growth, (b) exhibiting either *equifinality* (converging on the same end state from different beginnings) or (c) *multifinality* (divergent outcomes from similar beginnings), and (d) following an *epigenetic* course of development; in other words, the growth trajectory is highly susceptible to what Gottlieb (2003a,b) has termed “non-obvious experiential contingencies” as much as planned experiences such as instruction.

Further, prospective theories in developmental science suggest certain “rules” which operate to govern the progress of development in any area. Some of these include: that.

Another pseudosphere. This model was made by increasing one stitch every two stitches. Notice that it is considerably more crenellated than the previous pseudosphere. The hyperbolic radius here is about 3 centimeters. The model itself is about 10 centimeters in diameter.

Fig. 9 Crocheted hyperbolic planes. Crochet hyperbolic models by Margaret Wertheim. Photo © Institute For Figuring. <https://theiff.org/oexhibits/oe1e.html>.

Hyperbolic plane. Crocheted models of this space begin with a line of chain stitches. From there, one increases the number of single or double crochet stitches in every row, the rate of increase determining how rapidly the space will expand. This model is about 24 centimeters across and is made by increasing one stitch every 13. The structural integrity is achieved by using coarse, cheap synthetic yarn. Wool is nicer to work with (and gentler on the hands) but it does not produce the satisfying stiffness of synthetics. This model was made by Daina Taimina.

1. *A lower-level ability is only solidified by operating at a higher level.* In other words, “mastery” is only achieved by experimenting with higher level learning—not by repeating the lower-level skill over and over again. Therefore, restricting anyone’s learning to just the task at hand hampers the developmental process. Automaticity will not develop unless the possibility exists to practice any skill at multiple levels of difficulty.
2. *Experimenting initially with a higher level of functioning usually results in the learner reverting to using lower level processes.* However, rather than “regressions,” this utilization of earlier or familiar strategies have been denoted by [Granott \(2002\)](#) as “backward transitions” that are iterative processes solidifying what has been learned so that advancement can become more rapid (See also Templeton, this volume, for similar patterns in spelling development).
3. *Learners at any time are operating on multiple levels simultaneously.* In other words, the development of competence in any skill or activity means that the learner brings a range of skill levels ([Siegler, 1996, 2006](#)) to the task at hand and uses them according to the levels of difficulty perceived to be inherent in the task to be accomplished.

Andre’s writing sample reinterpreted

Let’s return to Andres’ writing sample (Figs. 3 and 4) from the standpoint of both retrospective and prospective models. First of all, in the retrospective model briefly discussed ([Whitehurst and Lonigan, 2002](#)), only the name—the first of 11 tasks—can be used—data from the other ten tasks must be discarded. This is a tremendous waste of information. Secondly, since only the figural features of the name are scored in traditional assessments of name writing, Andres’ name—although he demonstrates phonemic awareness of the individual letters—is no more useful in the model than any of the other four names written (see Figs. 5–8) by children who did not attribute any sound values to the symbols. Thus, not only is data lost in a retrospective view, but the conceptual complexity of the data itself is reduced to and conflated with that of the description of the visual aspects alone.

While “prospective” or developmental systems theories have been typically underutilized across many fields of education, psychology, and public health ([Luke and Stamatakis, 2012](#)), in child psychology there has been a shift from a Cartesian-framed analysis of behavior to what [Overton and Molenaar \(2015\)](#) have described as a “Process-Relational and Relational-Developmental-Systems” paradigm. The advantages of using a relational-developmental-systems framework orientation in discussing Andres’ performance are that *all the data can be used* and that the conceptual range that Andres demonstrates—from the phonemic awareness of the letters in his name to the use of one symbol per syllable, or one symbol per clause, to the iconic representation of both the word “oso” and his parents’ names can be interpreted according to “overlapping waves theory” ([Siegler, 1996](#)) as well as the following principle of developmental theory that “within-child variability tends to be greatest during periods of rapid learning—though substantial variability is present in relatively stable periods as well” ([Siegler, 2006](#)).

For Andres, then, the conceptual range within which he operated at the time this sample was collected, may well have presaged a more rapid learning toward a conventional understanding of the uses of written language than perhaps other children whose writing of the 11 tasks, conceptually at least, were more uniform. However, further follow-up into the kindergarten year was not a part of the study ([Tardibueno, 2006](#)), and somewhat limits a longitudinal observation and interpretation of these children’s ultimate trajectories in learning how to write in their heritage language and in English, the language of instruction in school.

Bilingual children learning to write in Chinese and English

Finally, in addition to research with Spanish/English emergent bilingual speakers, we have conducted a series of studies with beginning bilingual/biliterate children learning languages which differ in language structure and orthography such as Persian (Mirzai, 2002), Chinese (Tsai, 2007; Yaden and Tsai, 2012) and Korean (Kwak, 2006). With young, kindergarten Chinese/English bilingual children, the following patterns have been observed (Tsai, 2007; Yaden and Tsai, 2012).

Unlike the Spanish/English emergent bilingual studies, where children were only interviewed once with several tasks, Tsai (2007) used a microgenetic research design to measure children's understanding of each written task or trial in multiple sessions over a period of 3 months. These bilingual Chinese/English children were receiving instruction in Chinese literacy after school in Los Angeles for 5 h a week while attending local kindergartens where all instruction was conducted in English. All but one of the children spoke Mandarin at home. However, all children conversed freely in English during the study sessions, although we did not test specifically for language proficiency.

Some of the patterns already discussed in this paper appear in the following displays. For example, in Figs. 12 and 13, the child shows a “backward transition” in Chinese (Fig. 12) after the first two sessions, from a syllabic or word interpretation of whole composite characters and their semantic and phonetic components to a prior interpretation of objective differences only such as the number of strokes or not recognizing the 3–4 component structure of the composite character. In interpreting English script (Fig. 13), a level 2 indicates primarily that the child interprets the string according to visual characteristics only, and not to any linguistic segment. This pattern is stable for a month, with nearly every task being scored at Level 2. Beginning in November, however, much more fluctuation appears, both up and down.

Figs. 14 and 15 offer another example of variations or “punctuations,” following Gould and Eldrege (2002), after periods of a stable understanding of interpreting both Chinese and English scripts. The child's knowledge of Chinese is higher than English

Fig. 12 A pattern of “backward transition” in the interpretation of Chinese characters in the writing of an emergent Chinese/English bilingual kindergartner. Note. Writing sample in Chinese exhibiting a “backward transition.” For all subsequent figures, the Y-axis represents increasing levels of conceptual sophistication and the scored level of each task (child's name, mother's name, father's name, etc.). The X-axis represents number of total trials. Tasks repeat with each date segment. Figs. 12–21 from Tsai, T., 2007. A Microgenetic Analysis of English/Chinese Early Writing Development (Publication No. 3291823). Doctoral dissertation, University of Southern California.

Fig. 13 A pattern of “backward transition” in the interpretation of English letters in the writing of an emergent Chinese/English bilingual kindergartner. Note. Writing sample in English representing punctuation after period of stability.

Fig. 14 A pattern of “ordered fluctuations” after a period of stability in the interpretation of Chinese characters by an emergent Chinese/English bilingual kindergartner.

Fig. 15 A pattern of “ordered fluctuations” after a period of stability in the interpretation of English letters by an emergent Chinese/English bilingual kindergartner.

Fig. 16 A pattern of consistent “ordered fluctuations” in the interpretation of Chinese characters by an emergent Chinese/English bilingual kindergartner.

until the last session when the child begins to relate English letters and patterns to syllabic and phonemic segments. These graphs show what [Granott \(2002\)](#) has termed “ordered fluctuations” in the sense that the variations regularly vary between certain levels in both Chinese and English, until the last session in English where the variation becomes wider and the trend toward greater understanding of the English system seems probable. Again, it is clear that this child also operates on multiple levels of conceptualization in both languages.

The following displays ([Figs. 16–21](#)) show that becoming biliterate in any two languages offers varying patterns of growth. In [Figs. 16](#) and [17](#), the child demonstrates extremely ordered fluctuations in both languages.

In [Figs. 18](#) and [19](#), however, this child shows variation of understanding the tasks in the second language (English, [Fig. 18](#)), but not the first (Chinese, [Fig. 19](#)).

Finally, [Figs. 20](#) and [21](#) indicate that this child exhibits variation across several levels of conceptualization from task to task, from month to month in both the heritage language and English.

Fig. 17 A pattern of consistent “ordered fluctuations” in the interpretation of English letters by an emergent Chinese/English bilingual kindergartner.

Fig. 18 Variation of conceptualizations about the function of English letters by an emergent Chinese/English bilingual kindergartner who learned English as a second language.

Fig. 19 A stable conceptualization in the interpretation of Chinese characters by an emergent Chinese/English bilingual kindergartner.

Fig. 20 Wide within-task variations of conceptualization in the interpretation of Chinese characters by an emergent Chinese/English bilingual kindergartner.

Fig. 21 Substantial within-task variations of conceptualization in the interpretation of English letters by an emergent Chinese/English bilingual kindergartner.

It is important to add that much more detailed study of the children’s home environments as well as the classrooms for learning English and Chinese would be needed to begin to understand the sources of variation or stability, for that matter. Such design features, however, were not built into this particular study.

It suffices to say, however, even without knowing where the particular sources of variability might lie, that any child’s learning of a written system of any language will exhibit, most likely, some of the types of variation demonstrated in these studies. And, if so, then the implication for models of early literacy is clearly that they become able to incorporate such diversity and variation as Paris (2005) and our studies (see Yaden and Tardibuono, 2004, 2011; Yaden and Tsai, 2012) suggest.

Conclusion

An oft-quoted passage of Vygotsky’s from the *Prehistory of Written Language* related to the teaching of writing to young children states,

If we should want to summarize the practical requirements and express them in a single position, then we could say that consideration of the problem leads us to the requirement to teach a child written language and not writing the alphabet (p. 147).

Or in the cases of scripts which index other linguistic units, not to focus so much on those forms either, but rather as Olson (1994) has suggested—teaching children about what it means to “take” meaning from any script—what are the larger purposes of being literate in any society?

Developmentally speaking, our contention is that retrospective models of early literacy such as depicted in Fig. 2 expect us, rather, to demand a slavish focus on the alphabet and figural convention. However, prospective modeling and current microgenetic, developmental theory (cf. Overton, 2015) urges us to do the opposite, as did Vygotsky, Piaget and other developmental theorists (cf. Bronfenbrenner, 2005; Edelman, 1992; Tomasello, 2019). In other words, embrace the complexity of the developmental processes and as Vygotsky further argued “bring the child to an internal understanding of writing” in whatever language that may be.

What can cognitive neuroscience contribute to an understanding of literacy and literacy education (in the general sense used by school and teacher educator faculty, entailing language, reading, writing, and other systems of symbolic representation for communication, learning, and thought)? To date, the answer is not as much as some may believe, particularly advocates for a brain-based education (O'Mahoney, 2021; Sousa, 2014) or a science of reading (Burkins and Yates, 2021; Seidenberg et al., 2020). To justify our restrained assessment, we review mainstream research findings and theoretical constructs from the neuro- and related life-sciences in hopes of clarifying misunderstandings about reading-relatable neuroscience, misunderstandings often shared and reiterated by teacher educators, journalists, marketers, and educational policy advocates. To better inform educational applications, we propose reliance on a complementary and comprehensive life-science narrative about literacy development.

Specifically, we propose a distinction between narrow-gauge and wide-gauge pathways for connecting neuroscience to education. Narrow-gauge approaches rely on compellingly arranged facts, claims, and findings from cognitive neuroscience to justify theoretical constructs from cognitive educational psychology (e.g., as found in brain-based education and educational neuroscience; cf. Price, 2017; Thomas et al., 2020). This foreshortened narrow-gauge view is well disseminated and seems unproblematic for non-specialists to grasp in part because the claims are very familiar, having been made by cognitive theorists in education and psychology for nearly 70 years (Hoffman and Deffenbacher, 1992; Pearson and Cervetti, 2013). Syntheses of this work, as we shall include in this review, are certainly of value. But cognitive models are not without their critics and in the hands of non-specialists can act as rhetorical springboards for interpretations requiring a broader understanding for adequate justification (e.g., for educational policy or decisions on instructional method or curricular design). Too often the result are claims about "scientific" reading or learning based on assumptions of abbreviated isomorphism suggesting a computational physiology improbably shorn of biological constraint or socio-emotional intention, and further confounded by epistemological confusions and theoretical incoherence (Busso and Pollack, 2014; Howard-Jones, 2014; Hruby, 2012).

In contrast, we hold that the neurosciences can suggest a great deal about what it means to be a neurologically endowed and symbolically capable organism when neuroscience is synthesized within a wider array of life sciences (e.g., genetics, cytology, endocrinology, systems biology) and theory from life science-adjacent fields (e.g., developmental science, cognitive ethology, evolutionary psychology, philosophy of mind or neuro-philosophy). Such syntheses make cohesive sense of neurobiological processes in context over time and how they can give rise to symbolic communication as in natural human language and literacy. A fuller neurological view would include sufficient life science background and metatheoretical support to clarify, among other things, how nervous and endocrine systems develop, how they evolved in the first place, what constraints they impose and affordances they allow, how symbolic representation as a communicative form can emerge within those constraints, and thereby how *homo sapiens* evolved to develop natural language, symbol use, and the cultural affordances of literacy. Conversely, the mere charting of the functional neuroanatomy of the cerebral cortex by the light of cognitive models of mental process is insufficient to warrant an understanding of how humans employ literacy beyond what literacy researchers relying on cognitive models understand already.

What we encourage, then, is a naturalized view of literacy grounded by conciliatory assumptions from the life sciences useful for educational applications (cf., Gee, 2021; Sigman et al., 2014). Conjoining life-science informed insights about living organisms and systems with mainstream scholarship in literacy education could provide the latter with a refreshment some have argued is needed

(Reinking and Yaden, 2020). We acknowledge that, at this early juncture, theoretical advance is more likely than empirically demonstrated instructional guidance, but for the same reasons more necessary, preliminary in both senses of the word, formative and prefatory.

Useful knowledge about the neurophysiology of reading

We begin with a focus on reading processes and their development as an example applicable to literacy education more generally. Reading processes (what goes on in the mind when a reader reads) have long been a central focus in literacy education research and have been central to psychological research since its inception (e.g., Huey, 1908). As a result, research and theory on reading processes, contexts, development, and instruction is richly diverse, as a review of the field's major handbooks will demonstrate (e.g., Alvermann et al., 2019; Christenbury et al., 2009; Israel, 2017; Moje et al., 2020; Neuman and Dickinson, 2011; Rowsell and Pahl, 2015). Reading processes have been defined statistically by behavioral factor analyses since the 1940s, parsed by models from cognitive psychology since the 1960s, and theorized by analogy with information processing systems since the 1980s (Alexander and Fox, 2019). Since the 1990s, cognitive neuroscience has focused on neurophysiological correlates to functions identified in those earlier factor analytic and cognitive models of reading (Goswami, 2015; Hruby, 2017; Hruby and Goswami, 2011, 2019).

Meanwhile, the sociocultural turn in educational research since the 1980s has broadened the study of reading instruction to include writing instruction, language and second-language development, disciplinary literacies, technology-related and popular culture literacies, and the effect of socio-emotional, societal, economic, cultural, political, and ecological contexts for literacy learning (e.g., Alvermann, 2009; Gee, 2001, 2013; Gillen, 2015; O'Brien and Rogers, 2016; as well as the panorama of topics and perspectives in this volume). Tied tightly to theoretical models of computational cognitive process, the narrow-gauge track between cognitive neuroscience and literacy instruction has appeared disengaged from if not unsympathetic to this sociocultural turn. By contrast, wider-gauge educational neuroscience informed by naturalistic understandings of human development could be more complementary to literacy's sociocultural extension.

Technical issues

The techniques used to correlate neural activity with mental processes, such as positron emission tomography (PET), magnetic resonance imaging (MRI), or electroencephalographic (EEG) techniques, date to the 1960s, but strategic combination and technological refinement, in tandem with ongoing advances in computational power, have led to more precise contemporary methods. One result has been brain imaging: the vibrant rainbow-colored illustrations of functional neuroanatomical correlates that today adorn research reports, magazine covers, and popular websites. Non-specialists can be impressed by such images without fully understanding what they represent. Nonetheless, they are persuasive. Researchers have found that scientific reports illustrated with brain images are more compelling than the same reports with data tables or bar graphs (McCabe and Castel, 2008), and that non-specialist readers find psychological reports that refer to neuroscience more believable than the same that do not, even when the neurological explanations are irrelevant, contradictory, or illogical (Weisberg et al., 2008). "Neuromyths" held by educators have been an ongoing concern for neuroscientists and educational sociologists alike (Hughes et al., 2020; MacDonald et al., 2017; Worthly et al., 2021).

Non-specialist should know that brain study imaging is only superficially akin to X-rays, ultra-sounds, or medical MRIs. Contrary to common parlance, the brain does not "light up," and brain images are not photographs of the brain in action. The illustrations are in fact color-coded statistical charts from data sets averaged across research participants usually subtracted between two conditions and the result overlain on a normative model of a human brain. There are several of these normative brain models available, and their identification of regions, gyri, and sulci somewhat differ. Moreover, just as everyone has a face, but not the same face, everyone has a brain, just not an identical one. To get the data from different subjects in brain imaging studies to align to the coordinates of a normative model, a certain amount of manipulation is required. In other words, at first blush, brain charts give a misleadingly consistent impression of what "the brain"—implying all brains—look like and do when, in fact, there is a great deal of variation in neurophysiological anatomy and its functional purposes between and within human subjects that by necessity is obscured in the final images. When distilled by popular media for wider dissemination, a view of functionally necessary human homogeneity, both false and unhelpful, is promulgated. Critical consumers of these images need to remember they are as much the product of the models, methods, and technologies employed to produce them as they are of the underlying phenomena being investigated.

The blurring between what can be discerned from subject set averages and the characteristics found in specific individuals is notable in developmental studies, as well. Developmental trajectories, at different scales of physiological, functional, and chronological analysis, differ between and within individuals over time, a fact occluded by averaging subgroups in search of robust trend-lines. Brains are generally structured and highly plastic at birth but take on their effective functionality through learned response to their environments throughout the lifespan, and both environments and initiating (and ongoing) conditions in the brain differ between individuals and diversify over the lifespan. The result is that equally functional behaviors are possible from structurally

“irregular” brains, and seemingly similar brains can be surprisingly diverse in their functionality and behaviors. This is clearly the case when reviewing the changes that can occur in the brain after successful reading instruction or intervention (Barguero et al., 2014; Chyl et al., 2018; Kukona et al., 2016; Meyler et al., 2008).

As impressive as the technical advance of imaging technologies has been, precision is an ongoing vexation (Churchland and Abbott, 2017). Magneto- and electroencephalographic techniques are more precise temporally, parsing the electrical or magnetic field signature of neural activity to 100ths of a second, but their spatial precision is poorer than other methods, and deteriorates as the signal source moves away from the surface of the cerebral cortex. Hemodynamic methods, such as fMRI and PET, are more precise spatially but are less precise temporally, capturing changes in glucose or oxygen uptake in blood flow within brain regions of interest (ROIs) over nearly a second or more (a figurative eon in the world of neural activity). Results on similar experimental conditions from these two categories of technique often mismatch as neither measure neural activity directly, and spurious (non-neural) activity in the brain can blur results further (Jorge et al., 2014; Rosa et al., 2010). However, newer methods are improving the ever-evolving state of the science, through multiple matched comparisons (e.g., Bonhage et al., 2015; Koch et al., 2016; McCormick, 2021), or with newer techniques suitable for human study such as diffusion tensor imaging of white matter tracts (Cummine et al., 2015), transcranial stimulation (Rothwell, 2018), or electrode implantation (Themistocleous et al., 2017).

Areas of activation that are equally necessary to both conditions in a subtractive design will disappear in the final image; the differential is only of areas *uniquely* active between the two conditions. This is understood by neuroanatomists, but the distinction is often lost on non-specialists who believe what is being visualized is, for instance, “where in the brain we read letters,” etc. And the more highly specific the anatomical loci of a functional dedication reported in a study, the more likely the result is a false positive. Statistically, a great deal of noise reduction is necessary to create images representing neatly modularized regions of activation, and the crisp modular boundaries typically presented in brain images are, again, more an artifact of the methods and technologies employed than they are of the underlying phenomena being explored. Setting noise thresholds involves a degree of creative approximation guided by the search for a best-match and compelling image. The percentage of participants whose data are eliminated from analysis as outliers (failing to average neatly with the majority) can run as high as 40%, drastically reducing already arguably inadequate subject set sizes (Marek et al., 2022). Most studies finish out with single- or low double-digit ns (approximately 25 on average; Szűcs and Ioannidis, 2020). Concerns over study design and statistical inadequacies have an ongoing history within the neurosciences (e.g., Button et al., 2013; Frégnac, 2017; Poldrack et al., 2017; Ramus et al., 2018), with current estimation of false positives reported in published cognitive neuroscience studies running well over 50% (Szűcs and Ioannidis, 2017, 2020). This can partially explain lack of successful study replication, the high variability of loci correlated with specific processes or functions, and why the results of metaanalysis or careful synthesis are so diverse (Marek et al., 2022).

Although the issues outlined above require a more sober assessment of neuroscience related to reading, certain *general* results are well demonstrated. Our intention in noting these issues is not to discourage belief in the potential value of neuroscience for informing fresh narratives about the nature of reading, literacy, or symbolic thought in education, but to underscore the potential, now broadly realized, for vernacular misunderstanding, misappropriation, and misuse wherein the pretense of evidence is employed to promote possibly inadequate or even harmfully inequitable literacy policies, programs, and products (Compton-Lilly et al., 2020; Hruby, 2012; Vandenbroeck, 2017). Turning educators into neuroscience experts by inundating them with a welter of titillating images and factual tidbits is an unlikely and unnecessary proposition. We propose a more narratively cohesive approach, synthesizing a theoretical view of human learning informed by life and developmental science and life science-informed philosophy of mind and of language to connect the sciences of human change (including neuroscience) with current theory and practice in literacy education.

A narrow-gauge synthesis of neuroanatomy related to reading

To provide an example of a narrow-gauge review of mainstream findings from cognitive neuroscience related to reading processes, we begin with the Simple View of Reading (Gough and Tunmer, 1986), which distinguishes decoding processes (D) from language comprehension processes (C) in the measurement of reading comprehension (R; i.e., reading as measured on a standardized reading comprehension test). Reading is thus said to be the product of students’ decoding skills and their language comprehension ability. That is, $D \times C = R$. As a result, adequate performance on R requires adequate performance in both D and C, although, as research has revealed, much else is also required (cf., Hoffman et al., 2020; Duke and Cartwright, 2021). Literacy researchers and teacher educators traditionally subdivide decoding to print concept, alphabet knowledge, phonemic awareness, phonics accuracy, sight word reading, and fluency (Gough, 1972; Shanahan, 2005; Stahl et al., 2020). Language comprehension has been subdivided into language familiarity, symbolic and strategic reasoning, prior knowledge, and sociocultural or linguistic environment (Hruby, 2020; Pearson et al., 2020). Neuroscience studies have demonstrated correlations between most of these categories, or their subdivisions, and specific cerebral loci.

Fig. 1 Putative brain regions associated with different stages of morphological processing. Orange areas refer to modality-specific written word processes. Purple areas to modality-specific spoken word processes. Turquoise refers to putative a-modal processes. Key: PFG, posterior fusiform gyrus; AFG, anterior fusiform gyrus; STG, superior temporal gyrus; SMG, supramarginal gyrus; AG, angular gyrus; MTG, middle temporal gyrus (although here rather posterior); ATL, anterior temporal lobe; IFG, inferior frontal gyrus. From Gwilliams (2019), depicting possible language and reading loci of left-side of the cerebral cortex.

Decoding

Text decoding processes, wherein sequences of letter shapes on a page or screen are interpreted or recognized to known word forms, follow two distinct trajectories in the brain, both beginning in the occipital lobe where visual processing for letter shape identification occurs (Paz-Alonso et al., 2017; Rueckl et al., 2015). The first route traces a dorsal (upper) trajectory through the left parietal lobe in an arc toward the left angular gyrus (AG; see Fig. 1 for acronym loci) and supramarginal gyrus (SMG) at the temporal-parietal transition. The SMG is where neural activation correlates with study subjects sounding out letters or letter groupings to identify auditory word forms (Oberhuber et al., 2016) triggering recognition of a sound pattern in the left superior temporal lobe (STG) with a neural nodal nexus for word meaning into the left medial temporal gyri (MTG). Readers who demonstrate difficulty sounding out words fluently demonstrate atypical activation in the SMG and loci downstream along this trajectory (Gori et al., 2014).

The second decoding route traces a ventral (lower) trajectory, again, from the occipital lobe at the back of the brain for visual letter shape processing, along the inferior occipital-temporal sulcus, parallel to the inferior longitudinal fasciculus, through the fusiform gyrus (AFG and PFG in Fig. 1), a region often dubbed the *visual word form area* (VWFA), or *the brain's letterbox* (Dehaene, 2009). The VWFA is adjacent to areas for identifying faces and common objects (presumably by selecting for higher salience characteristics in a perceived visual pattern or learned prototypical sequence; Vogel et al., 2014). This is where orthographic patterns are recognized as "sight words," or familiar letter sequences, before routing forward into the temporal lobe (MTG, ATL), again, to activate a word's nodal nexus for meaning (Dehaene et al., 2015). Whereas emergent readers rely more on the dorsal-auditory route as they master their decoding skills, possibly facilitated by being explicitly taught to do so in school through some form of phonics instruction, fluent readers, such as literate adults, typically rely on the more efficient and rapid ventral-orthographic route. Readers thus demonstrate a shift from relying on the dorsal (phonemic processing) route to the ventral (orthographic processing) route for most word-form decoding as they mature into fluent readers and demonstrate increased reliance on sight words (Martin et al., 2015).

Average intermediate grades readers are also more likely to activate the ventral route compared to peers who demonstrate persistent decoding difficulty (Brem et al., 2020; Huettig et al., 2018; Martin et al., 2016). The absence of direct neural connection between the SMG and the VWFA suggests that fluent sight word reading is not the sounding out of letters so automatically a reader does not know they are doing it. Rather, occipital-temporal activation appears to be a form of visual pattern or sequence recognition similar to facial recognition or familiar object recognition, both of which activate adjacent and right analogous areas of the brain. Just how this works at the level of neural tissues and networks is a matter of speculation (Chen et al., 2019; Goswami, 2019; Gwilliams, 2019). It is possible the recognition of visual patterns relies on neural assemblies similar to those for sound-pattern parsing of rhythms, syllables, or morphemes (De Vos et al., 2017; Goswami, 2020; Verhoeven and Perfetti, 2011).

In the span of milliseconds, the subvocalization of sight words occurs *after* word-level comprehension is inaugurated, even as syntactic and semantic integration is engaged (although these activations seem simultaneous in conscious awareness). [Chen et al. \(2019\)](#) found that the VWFA significantly connects not only to language processing areas by way of the temporal lobe, but also directly to areas in the superior parietal cortex for quickly directing nonconscious attention, possibly facilitating pattern anticipation and recognition to most probable (i.e., coherent) perceptual pattern confirmation. Developing readers likely employ both dorsal and ventral routes redundantly for some time, using the dorsal route as “training wheels” to scaffold the ventral route until it can handle run-of-the-mill word identification needs effectively ([Martin et al., 2015](#)). That is, teaching children to sound out every letter of every word (in the SMG) is how teachers unintentionally foster children’s overlearning of the orthographic regularities (in the VWFA) for automatized recognition of print.

Activation through developed white matter tracts (bundled and myelinated neural pathways well matured by use and thus efficient in their functions; ([Wandell and Yeatman, 2013](#))) occurs within a matter of milliseconds and runs in both directions along a fascicular tract: every bit as much from frontal and superior areas of the brain for attention, interpretation, and meaning, to posterior and inferior areas for perception and sensation as in the opposite direction (from the “start” of reading) in sensation and perception forward to word meaning, constructed scenario, and interpretation ([Cartwright, 2012](#)). Possibly due to cultural traditions privileging empiricism over rationalism in anglophone epistemology, self-reflection by members of that tradition, by whom most of the research of this type has been done, enjoy the confident illusion that subvocalization of sight word texts leads to, rather than is the result of, a search for context-relevant meaning. But in coordinating a conscious response to a text, a great deal of back and forth occurs between lower-order (and fairly modular) nonconscious processes across the brain ([Liebig et al., 2017](#)). The infinitesimal timescale of these neural processes should not be confused as analogs for conscious word attack strategy or sequencing of reading instruction over weeks to years.

Comprehension

Literacy educators often refer to *comprehension* as a solitary construct, one of the so called “Five Pillars of Reading” (along with phonemic awareness, phonics, fluency, and vocabulary; [Shanahan, 2005](#); [Cassidy et al., 2010](#)). Literacy researchers have extensively explored four language comprehension subcategories: (a) *language familiarity* (e.g., knowledge of vocabulary, common grammatical structures, idioms, tropes, discourse features); (b) *symbolic and strategic reasoning ability* (e.g., lower order abilities, such as comparison, categorization, analogy, inference, determination of priority, as well as higher order abilities for strategic problem solving, such as text-level assessment, questioning, summarization, graphic analysis, reviewing, and discussion with others); (c) *knowledge base or prior knowledge* (of self, sociality, world, content, “common sense,” culturally normative beliefs, etc.); and (d) *linguistic or sociocultural environment* (from which a language user learns their language, and in which they employ and practice it to intentional, normative, and self-correcting ends) ([Hruby, 2020](#); [Pearson et al., 2020](#)).

For a first pass on how language comprehension develops (see [Fig. 2](#)), this four-component view—literate environment, language familiarity, symbolic reasoning ability, and knowledge base—may seem sufficient, although the model would be profitably extended with the incorporation of socio-emotional intention, metacognitive motivations, and agentive identity (see [Hoffman et al., 2020](#)). But as it is, the subprocesses contained within each category complicate the construction of cognitive neuroscience study designs. Parsing reality (e.g., anatomical function) “at the joints” (i.e., locating areas of activity in the cerebral cortex relevant for comprehension subprocesses) is tricky and can too easily become self-fulfilling prophecies. Studies employing general categories from linguistics has led to areas identified as relevant for lexical, syntactic, and semantic processing ([Hruby and Goswami, 2019](#)). Studies of consciousness and meta-cognition, presumed requirements of comprehension in school settings, locates multiple areas elsewhere ([Carreteiro and Figueiro, 2017](#); [Pace et al., 2020](#)) (For the theoretical quagmires lurking in the topic of consciousness see [Chalmers, 1996](#); [Koch et al., 2016](#); [Wendt, 2015](#)).

Fig. 2 With each step in the trajectory, left to right, the development of a category supports others, such that the development of language use by a child adds to the density and complexity of the linguistic environment from which it learns language; which in turn fosters the development of the child’s symbolic reasoning (language being the first and primary symbol system a child must master), thereby enriching the language familiarity and linguistic environment from which it develops; finally, symbolic reasoning, language, and environment develop the child’s knowledge base, for humans do not merely use language and reason symbolically, they do so about matters, those matters becoming knowledge. The categories are not stages, but an ongoing set of nested and recursive developmental processes ([Hruby, 2020](#)).

Because the theories, models, methods, and research designs employed in this work have as much to do with the apparent functionality of the loci as the underlying activity being studied, the current neuroscience literature on *reading comprehension* lends an unfortunate “now you see it, now you don’t” impression to which subcomponents matter, when, and where. The imprecision of localization methods is amplified by the functional and anatomical foci being too broadly bounded to indicate the neural connections and networks involved or the structure of their “processing,” but also too tightly bounded to be inclusive of all the multiple processes operating at differing scales of structure and time required for conscious understanding. Although methodological reductionism in parsing the brain’s complexity is necessary, it may inadvertently lead to unjustified theoretical reductionism.

The sharply modular representation of brain loci created by imaging technologies can be misleading. For instance, vocabulary definitions are not “stored” or “recorded” in the left medial temporal lobe, as shorthand reference may suggest. Word meaning involves networks of neural lacing across many areas of the brain including for sensation, motor activity, emotional arousal and control, executive strategy, and even sub-cerebellar areas for emotion in the limbic lobe, cerebellum, and brain-stem (e.g., Alvarez and Fiez, 2018; Damasio, 2021; Venkatraman et al., 2017). These neural nettings are insufficient in volume to appear in whole brain imaging studies, but they converge in the temporal as nodal clusters large enough to be reported as significant, hence the “localization” of word meaning in the temporal regions. Similarly, a focus on any cognitive process will image correlated activity unique for that process, while equally important factors and areas shared with the comparison condition will go missing.

Taking these warnings to heart, language comprehension processes trace through two main routes as with decoding: an upper (dorsal) pathway and a lower (ventral) pathway (see Fig. 3). The dorsal pathway traces from speech sound processing (SMG) to syntactic processing in the left inferior frontal gyrus (IFG), possibly for analyzing morphemic grammatical markers, and to a more varied dorsolateral set of areas for semantics and situation modeling. The ventral pathway traces from the medial temporal and adjacent areas (activated for lexical access or word meaning) into the IFG and adjacent dorsolateral frontal areas for syntactic and semantic integration (Catinelli et al., 2013; Walenski et al., 2019).

Neuroscientists have dependably and repeatedly correlated activation in the left temporal lobe with lexical recognition and word comprehension (Schuster et al., 2021), left inferior frontal gyrus (LIFG) with syntactic tasks (Henderson et al., 2016), and dorso-lateral and orbito-frontal, medial cingulate, and superior parietal cortex with higher-order and a-modal semantic processing (Deniz et al., 2019). Still, how neural activity incorporates these levels of language, integrating lexical meaning and syntactic structure into sentence-level comprehension, is far from established (Arana et al., 2020; Bonhage et al., 2015; Gwilliams, 2019; Hagoort, 2019; Takashima et al., 2020).

Fig. 3 Potential cerebral pathways and ROIs for reading in left cerebral cortex; Blue arrows—decoding pathways; solid red arrows—language comprehension pathways [vocabulary, grammar, clausal meaning]; dotted red arrows—a-modal comprehension pathways; green arrows—semantic and scenario pattern prediction and confirmation pathways; darker green areas: semantics and scenario; lighter green area: syntax; red-orange areas: emotional meaning associations; magenta area: word sound patterns; orange area: auditory processing; periwinkle: orthographic processing.

In comparison to the comprehension related research, the use of cognitive models to guide interpretation of neural activation during decoding seems less problematic, but this illustrates again how theoretical framing drives the interpretation of data. Because decoding is described as symbol identification and association, and because symbols map easily as artifacts of a computational processing system (computers being quantified symbol re-shufflers and modifiers), the central metaphor assumed in cognitive process modeling of the mind as an information processing system appears confirmed in decoding studies (Brette, 2019; Martin and Baggio, 2019). Word prediction and grammatical structure can be parsed similarly as pattern recognition of syntactic and semantic sequences (e.g., as demonstrated by messaging apps on smart phones) (Friederici et al., 2017; Nieuwland, 2019). However, determining the loci of conscious comprehension is more conceptually challenging. The computational metaphor implied in cognitive models presumes internal coherence as a defining characteristic, which might make sense were neural systems inherently symbolic in nature (a questionable assumption on biological grounds). But calculation of symbols or data points is an analogy of limited application because comprehension also requires non-cognitive internals such as emotional state and hormonal arousal, and externals such as situational and socio-emotional context. Of course, any of these factors may be reduced to quantitative categories (Barsalou, 2017; Boeckx and Grohmann, 2013), but rendering phenomena symbolic through quantified nominalism does not make the phenomena itself symbolic in nature (Seth, 2021).

Additional neural factors relatable to reading

Additional scales of analysis beyond sequences of linguistic indices—orthographic, lexical, syntactic, semantic, textual, or narrative—and systems for integrating them are necessary to appreciate the priority-driven nature of human attention led by emotive factors from basic associations and desires—thirst, hunger, warmth—to higher-order emotional and social associations and desires (Damasio, 2021; Grossmann, 2013; Immordino-Yang, 2015). These intentionally direct the nervous system toward functional satisfaction conditions primed through prior experience, whether perceptual, strategic, socio-emotional, or linguistic, thereby driving interpretation and anticipation on behalf of those conditions. These entailments require more than studies of neuroanatomical correlates to reading-relevant behaviors. Time and sequence bring into view the recursive bio-developmental processes that allow the predictions and confirmations guided by socially normative expectation central to conscious understanding (Grossmann, 2013; Immordino-Yang and Gottlieb, 2017).

Even in a cognitively restrained view, there is more to reading for meaning than decoding, wherein shapes are translated into recognizable sound patterns, plus language comprehension, wherein language is reduced to vocabulary, grammatical relation, and the woolly catch-all of semantics (Cervetti, et al., 2020; Snow & RAND Research Study Group, 2002). As even mid-20th century anglophone analytic philosophers were cognizant, meaning making extends across normative social relations and visceral or cultural intentions that derive signification from those interrelations (Austin, 1962; Rorty, 1978, 1990; Sellars, 1957/1997). From that view, language (and thus knowledge) evolved chiefly not for representation, but for intention and inference sharing. Hence, community-elicited desire, belonging, identity, autonomy, and other human articulations of *thumos*—ancient Greek for full engagement; “zest for life”; desire for recognition, dignity, or social position (Fukuyama, 2018)—are of a piece with the development of language, narrative, and learning to read for meaning in a literate society. We know of no cognitive or developmental literacy models in neuroscience that shadow these motivations.

However, studies confirm that sociality, emotion, cultural traditions, and the structures of societal-economic institutions present equally necessary variables for analysis (Altmann et al., 2012; Lee et al., 2021; Pace et al., 2017; Preckel et al., 2018). The potential of these factors for neuroscience research is explored in studies tracing socio-economic correlates with educational affordances and thus with brain development, or neurological correlates to degree of empathy (Brinch, and Galloway, 2012; Etchell et al., 2018; Falch and Massih, 2010; Lamm and Majdandzic, 2015; Pavlakis et al., 2015). But the weight of all that freight strains the axes of a narrow-gauge review of the literature. A wider gauge network may facilitate the inclusivity required of it all.

The development of a learner’s skills and knowledge base is driven by a pattern-detecting brain filtering experience in coordination with its sociocultural context, and this informs everything from “common sense” or normative assumptions of sequential probability to more precisely articulated theoretical, political, philosophical, or religious beliefs as frames of reference (Gee, 2013; Immordino-Yang and Yang, 2017; Kaplan et al., 2017). These together then inform and direct lexical attention with the granular detail and systemic organization afforded by linguistically mediated perception. To reduce reading to interpretively bounded “regions of interest” indicating neural “modules” is to impoverish literacy scholars’ understanding of the emotionally and culturally adaptive nature of reading development and behavior. It is not that biological elements do not matter, but that any one category of element cannot adequately represent the whole. Thus, the narrow track entices brain-based educators to the fallacy of insufficient metonymy as adequate analogy induced by the false assumption that limited data from cognitive neuroscience on decoding and language processes is a full or ultimate report. It is rather only a report on limited neurological phenomena; not on the behavioral, conscious, social, or cultural phenomena relevant to effective instructional decision making sought by educators. Moreover, the overt emphasis on how anatomical structure allows functional outcomes ignores how an impetus toward functionality over time allows emergence of adaptive structure (see Fig. 4.). And Additionally, the singularly inward gaze of cognitive neuroscience can unintentionally suggest inherent, decontextualized, and immutable causes for ability or disability.

Question Category	Definition	Example
The structure question	What is physically necessary for the behavior to occur?	What neuroanatomy, physiology, or spatial affordances are necessary for language or symbol use?
The function question	What does the behavior accomplish?	What does language or symbol use allow a human to do?
The development question	How does a propensity for the behavior express itself?	How does language ability or symbol use develop over time?
The evolution question	Under what circumstances was the behavior advantageous allowing it to be selected for as a species-specific propensity?	Why did language and symbol use emerge as unique characteristics of <i>homo sapiens</i> ?

Fig. 4 Tinbergen's Four Questions about animal behavior applied to literacy: an example. The first two categories of question—structure and function—are considered immediate or proximal causes. The second two categories—development and evolution—are considered ultimate or distal causes. (Adopted from Tinbergen, 1963). Other questions for human application might include the historical and political/economic.

Neuroscience research related to reading difficulties and dyslexia

The topic of developmental reading difficulties and disorders or disabilities is treated in other excellent entries in this volume. Here we will emphasize but one truth well understood in literacy education: students' difficulty with reading in real-time, or in the ability to develop grade-level reading skills over time, takes many forms and has many causes. Some of these may be decoding related, some language comprehension related, some related to other causes, none of them mutually exclusive and likely operating at various scales of developmentally accrued precedent with eventual higher-order impact on motivation to learn and identity as a reader (Elliott and Grigorenko, 2015). This complexity and diversity makes diagnosis and successful intervention of reading difficulties difficult, but never more so than when a blind eye is turned to the behavioral, cognitive, social, and neural particularity of the readers.

Notably, studies of functional neurophysiology between typical readers and readers with atypical difficulties present diverse results, generated by the various arbitrary boundary conditions used to distinguish contrastive categories (Chyl et al., 2021; Kuhl et al., 2020; Paulesu et al., 2014)—although in the case of neurological studies of reading development the distinctions may seem at times driven by surprisingly assertive vernacular shibboleths, such as that dyslexia is any and every kind of reading difficult (cf., Gabel et al., 2010; Peters and Ansari, 2019; Scerri and Schulte-Körne, 2010). To be generous, neuroscientists (and the technologists, data specialists, statisticians, psychologists, neurologists, graphic artists, and theorists with whom they collaborate) are not experts in the teaching of reading or its research base, and rarely seem to have consulted much applied research on the behavioral categories under investigation before studying their neuroanatomical or neurofunctional correlations.

As an example, most neuroimaging studies comparing typical readers to readers labeled *dyslexic* often cite, or at least paraphrase, a formal clinical definition in their introductory literature review defining dyslexia as a phonological processing disorder due to neurobiological irregularities (e.g., International Dyslexia Association, n.d.; National Institute of Neurological Disorders and Stroke, n.d.). Neurobiologically-based phonological difficulty is a generally accepted definition of dyslexia warranting neurobiological investigations seeking neuroanatomical or genetic atypicalities affecting the SMG, AG, and/or STG, that is, in the language sound processing areas of the cortex (Kearns et al., 2018). Yet in the methods section of said studies, it is nearly always the case that the dyslexic subjects have been selected on the basis of standardized reading assessment scores (for which, it should be remembered, $R = D \times C$; see Decoding subsection above) with no effort to exclude readers encumbered by language disparity rather than weak phonological processing, or to exclude those subjects with perceptual difficulties or disruptive comorbidities (e.g., ADHD, below average IQ) that might account for the impaired reading score, both being instances that would fail to qualify clinically as dyslexia. In other words, dyslexia is defined both as a specific phonological learning disorder and at the same time for subject selection as just any kind of difficulty with being able to read—now you see it; now you don't (cf. Norton et al., 2015; Peters and Ansari, 2019; Hendren et al., 2018; Pettigrew et al., 2016).

Depending on grade level, a varying percentage of subjects will struggle below the arbitrary cut score for reasons *other than* phonological processing difficulty, that is, for reasons other than dyslexia as formally defined (Huetting et al., 2018). Because subjects may score below the chosen cut score for reasons other than decoding issues, they are unlikely to consistently demonstrate atypical ROIs indicating neurobiological distinctions relevant to phonological processing—unless these are the result of, rather than the cause of, their reading difficulties (Kearns et al., 2018). This then presents a chicken and egg (cause and effect)

conundrum in the interpretation of noisy data that may lead, via confirmation bias and small subject sets, to the false positives of current concern. The situation calls for neuroscientists to take a closer look at their study designs, but also at mainstream reading research and its long-standing points of debate (e.g., Alvermann et al., 2019; Goodwin and Jiménez, 2020), and to consider the use of valid subskills diagnostic screening assessments to winnow subject sets more precisely before undertaking neuroimaging.

A shortcoming on the educational side of this cross-disciplinary confusion is mistaking studies of the brain while the subjects are engaged in reading-relevant behaviors as studies *on reading*. They are not; they are studies *on the brain*, that is, studies about neurological phenomena conducted by neuroscientists using neuroscientific methods, written up for publication in neuroscience journals peer-reviewed by, and intended for, other neuroscientists. Such studies are only peripherally about reading processes, and then only as neuroanatomically re-defined, but they are certainly not about reading instruction or reading development as it is understood in literacy education. Reducing reading to measures of blood flow is excessive reduction. Even if taken as a valid indicator of physiological changes in the brain, the data are not representing reading as measurable conscious understanding or instructional efficacy. Nor do such studies prove the validity of the cognitive models of mental process used to interpret the data; those are presumed true in the interpretation of the data and thus cannot be also a finding from the data. All that the successful use of such models demonstrates is that such models are useful for model-coherent data interpretation; the question of whether mental processes or minds actually exist as natural entities remains an open neuroscientific question (Churchland and Churchland, 2002).

Circular reasoning aside, to conflate levels of analysis, conscious and nonconscious, mental and physiological, anatomical and cellular, as if they were all identical or isomorphic, is indicative of category error (Han et al., 2019). In this way, the seemingly tight certainty of a narrow-gauge trek between neuroscience and reading-relevant behaviors can be misinterpreted by non-specialists suggesting it is the brain that reads, rather than the reader, or as *neuroscientific evidence for how to teach reading*, thereby misdirecting or misinforming reading instruction policies and law (Vandenbroeck, 2017). Greater attention to the dynamics of how higher-order and lower-order levels of analysis in complex systems conjointly transact, as in systems biology, is a potential conceptual corrective (e.g., Bassett and Sporns, 2017; Han et al., 2019).

The definition of dyslexia as an incurable, neurobiological disorder has been presumed for close to a century (Vellutino et al., 2004). Conflating the category of clinical (phonological) dyslexia with all “below basic” or “poor readers” (i.e., readers falling beneath a given cut score for a range of reasons) is unjustified. It does not escape notice that in most Western societies the latter group are disproportionally of color, of poverty, and often of foreign birth or immigrant parents and thus more likely second-language learners (Konishi et al., 2014). Research on phonological processing difficulty does not find for this correlation. Conflating these distinct categories of reading difficulty could perpetuate long standing cultural-historical dispositions to segregate people by disfavored characteristics presumed immutable. The call for more equitable funding for schools serving such students could be thereby undermined. Thus, to further marginalize underserved populations through misinterpretation of neuroimaging studies by thought leaders who likely understand very little about neuroscience, or about effective educational practice, or even about the social and economic impact of institutionalized segregation, could perpetuate and extend systems of structural racism and inequity.

That particular areas of the brain, such as the SMG, are the locus of phonological processing is not in much doubt (Church et al., 2011). That imaging results show significant differences in such areas when subjects demonstrate difficulty with phonological processing is not surprising (Dahhan et al., 2016). But to interpret differences reported from neuroimaging studies of those areas as evidence of inherent and immutable or incurable deficiency of already underserved populations without true or adequate longitudinal crosscheck is overreach. The design of cross-sectional studies that claim to show inherent deficiencies in *pre-readers* “at risk” for reading difficulty may someday be looked back upon as something far worse than weakly justified study design.

Neurobiology of reading

A belief in the immutability of human characteristics or potential is a reiteration of the nativist (nature) side of the nature-nurture debate, a relic of 19th and 20th-century Western psychology (Cobb, 2015; Overton, 2015). Nativism perpetuates a pre-modern Western belief in a steady-state world where nothing much ever changes (e.g., the acorn doesn’t fall very far from the tree). It was lent scientific credence through the theoretical posit of the *gene*, a unit of descent, put forth by the 19th-century Austrian monk Gregor Mendel who demonstrated that passage of traits through *genealogical descent* (i.e., as related to *kinship*, another pre-modern, aristocratic Western concern) could be quantified. After the discovery of the functional structure of DNA (Watson and Crick, 1953), a schism opened between those who held an interest in genealogy and persistence, and so relied on behavioral genetics (statistical and social) to track traits across generations, and those whose interest were biological and proteomic (empirical and developmental), and thus more focused on change processes and adaptation.

Obviously, in an overly broad sense, everything human is genetic as humans are multicellular life forms and cells rely on the proteins encoded by their genomes to function—but only in response to biochemical cues within nucleic, cytological, organismic and/or environmental contexts (Gottlieb et al., 2006). At no point in the life cycle is anyone a context-free genome. The initial functioning zygote (i.e., fertilized egg cell) formed by the fusion of genetic materials from two functioning gamete cells is a complete functioning cell responding to its intracellular context within functioning tissues within a functioning body, that body having functionally developed within presumably functional yet changing surrounds—physical, biological, nutritive, and for humans, emotional, linguistic, societal, and cultural—each level responding as necessary to maintain its capacity to function. In this, agent

and context are partners as much as are structure and function, change and stasis, or nature and nurture (Gottlieb, 2001; Overton, 2015). The preformationist idea that information exists within the genome as a context-free blueprint for the formation of structure is representationalist fallacy. In so far as genetic structure can be quantified by humans thereby giving it representational form, the information for any biological structure is as much found off-loaded in contextual specifics as in nucleic sequences, or alternatively as a matter of interrelation and transaction. This is to say, the information is not in or inherent to the organism, the protein, or the genome, but in the interrelationship of these entities with their guiding environmental surrounds to which they have evolved to effectively respond (Oyama, 2000).

There are no genome-wide assessment studies (GWAS) with sufficient ns demonstrating statistically significant genetic variants for dyslexia or propensity for reading ability. Given that approximately 3.4 million nucleotides per subject are mapped in a GWAS, approximately 20,000–30,000 subjects are required (e.g., as exists for studies of schizophrenia), with a p value threshold of 10^{-8} (see Derizotis and Fisher, 2017). The largest GWAS on dyslexia to date correlating dyslexia diagnosis with single nucleic polymorphisms (flipped nucleic pairs in the DNA sequence for a gene) failed to find variants significantly associated with dyslexia (Gialluisi et al., 2021; cf. also Derizotis and Fisher, 2017; Reader et al., 2014). Gialluisi and colleagues relied on available GWAS data from 9 different populations of European descent for a total n of 8546, of which 2274 subjects had been identified as dyslexic. Although the sample size is inadequate, it is the largest sampling to date. Other calculations, including correlations with comorbidities (e.g., ADD/ADHD, general learning disability), were more significant, but in any case rule out a clinical diagnosis of dyslexia for such subjects. (The Manhattan-plot results can be found at <https://www.nature.com/articles/s41380-020-00898-x/figures/1>).

Often cited in refutation to disappointing GWAS results, proponents of behavioral genetics (Mendelian analysis, e.g., Bishop, 2015) cast doubt on the value of GWAS insisting that mappings of actual genes and their variations reveal little about genetic effects; rather, direct observation of traits through inferential analysis of demographic data do. Asserting that identification of traits through social science survey instruments and interviews is more certain knowledge for understanding the biochemistry of cellular-level brain development than genetic assays of the sequential variants responsible for diverse developmental effects is a curious argument, one increasingly strained as the technology for mapping the genome has advanced and become commonplace (Carrion-Castillo et al., 2016; MacArthur et al., 2017).

Traits observed between siblings and twins demonstrate only heritability (characteristics found commonly within families, thus *genealogical*), not genetic variation in the strict biological sense, in other words, as distinct nucleic sequences coding for amino acids that make up proteins with potential effect on cortical development or neural function (Doust et al., 2020). Much is heritable that is not genetic in the biological sense such as first language, early income level, religion, community practices, family traditions, expressive behaviors, etc. (Kaplan et al., 2017). And then there are the effects of epigenesis (Lickliter and Honeycut, 2020; Pallarés-Domínguez, 2019). Twin adoption studies ignore the environmental consistency of shared gestation period and pre-natal environmental effects in development, and the fact that adoption agencies and governmental regulations restrict potential adoptive parents to those with certain socio-economic characteristics at variance with larger populations (e.g., a sufficient income, home stability, lack of criminal record or evidence of abusive behavior), or that most of those who adopt children likely have common reasons for doing so (Segal, 2021).

Assuming that neuro-genetic differences are the structural cause of a reading deficiency, that is, assuming still developing readers are suffering from an incurable neurobiological disorder, rather than a developmental correlate to a complex web of interacting environmental factors (Kershner, 2019; Weisberg et al., 2014), pays inadequate attention to parental education and literacy levels, socioeconomic status, inadequately funded and supported educational affordances, culturally maintained intergenerational effects, and debilitating chronic anxiety of parents from socio-economic condition and social-class stressors. Given that there are strong correlations between socioeconomic class, language development, and thus reading ability (Law et al., 2017), claiming already marginalized populations are disproportionately and incurably weak readers due to inadequate genes or brains denies other manifestly evident factors, or even perpetuates their effects as covert social subordination. If ever there was a need for a wide-gauge synthesis of available research about human adaptation and development by which to critique circular reasoning, affirmation of the consequent fallacy, egregious category error, and willful misinterpretation, student reading and learning deficiencies ought to be first among equals.

Literacy education naturalized: a wider-gauge view

We have suggested throughout this entry a distinction between narrow-gauge and wide-gauge approaches to an educational neuroscience of literacy development. We imply an analogy with rail transport, wherein narrow-gauge lines are typical for local or specialized conveyance (e.g., rapid transit, streetcars, industrial spurs, mining wagons). Wide-gauge lines transport over greater distances at higher speeds, with more powerful engines conveying more varied cargo and in greater volume (e.g., passenger and freight routes; high-speed rail).

Narrow-gauge indicates more specific and immediate connection, and brief is the distance between brain studies and their meta-analyses, or between the theoretical models that inform their designs and the data they produce (as when cognitive models of mental process suggest the functional utility of neuroanatomical correlates). Such focused narrow-gauge tracks play a crucial role in building larger systems of transdisciplinary inquiry. Yet a network of wider-gauge routes are required for longer distances

or more diverse needs and populations. In our usage, the wider gauge indicates transdisciplinary inquiry made manifest for a robust educational neuroscience.

It has been asserted before that an elongated trestle, wide gauge or not, between neuroscience and educational practice is “a bridge too far” (Bruer, 1997). The solution often suggested is to hoist the bridge across intermediary supports in a direct line: from neuroscience to cognitive neuroscience to cognitive psychology to (cognitive) educational psychology and thence to educational practice as hemmed by cognitive theory (Tommerdahl, 2010). But this offers only a single narrow route which suffers a loss of precision with each additional link, and, as noted in our introduction, it ignores literacy education’s socio-cultural turn. We instead propose routing support from the wider life sciences through three additional intermediaries to improve relevant access to education: bridges, in other words, from the life sciences to educational theory and practice via (a) developmental science, including developmental neuroscience (b) naturalized social science (drawing from life science theory), and (c) naturalized epistemology, as in current philosophy of mind, of biology, of language, and neuro-philosophy. For brevity we elaborate in 5 points.

1. *The developmental sciences.* The developmental sciences have long been highly invested in assumptions from the broader life sciences about the nature of living organisms, including human beings, and their capacity to change over time in response to environmental circumstances while ever remaining functional (e.g., Ayoub and Fischer, 2006; Boles, 2019; Fischer and Bidell, 2006; Greenberg and Partridge, 2010; Lickliter and Honeycutt, 2015; Tomasello, 2019). Developmental neuroscience and developmental biology are the switch gates between narrow gauge studies of localized brain function and wider-gauge syntheses of reading development across the lifespan in and out of school contexts (Wiberg et al., 2019).
2. *Developmental science is about change over time*, and we believe that is the unifying objective of education, at both the individual and societal levels. Nonetheless, whatever else humans can be described as—social, cultural, linguistic, ideological—they are most certainly biological and thus exhibit the adaptive developmental processes studied in the developmental sciences. The bio-ecological turn that began in developmental psychology in the 1980s (e.g., Bronfenbrenner and Ceci, 1993; Bronfenbrenner and Morris, 2007) has since carried forward into an ever more cogent and cohesive set of theoretical explanations for how developmental change occurs which we believe worthy of exploration by literacy researchers (for overviews see Bornstein and Lamb, 2015, and other editions; Lerner, 2015, and other editions). The influence of this domain has already emerged within educational theory (Nasir et al., 2021; Yaden et al., 2021).
3. *Life-science informed social science.* Life-science informed social science would include fields such as archeology, cognitive ethology, evolutionary psychology, biological anthropology, or ethno-botany. These offer empirical background for thinking about how natural language becomes developmentally possible in humans. They extend the biology of development and behavior into its transactional and ecological relationships over time. The life sciences remind social science that developmental capacities evolve to enhance sustenance, safety, and adaptive generativity (Berwick et al., 2013), an insight worth bridging to literacy research and classroom practice. Studies in neuroendocrinology on the self-regulating neuro-hormonal pathways directing emotional behaviors, social hierarchies, and trauma is a rich vein of research that is already contributing to studies on classroom community and exclusion. Postulating language as a form of animal communication may seem startling, but as a thought experiment on the meaning of meaning and its adaptations, it has its virtues (e.g., Deacon, 1997; Tomasello, 2019). And comprehensive analysis of the entwined causal relations between *structure, function, development, and evolution* (Tinbergen’s famous four questions; Beer, 2020; Nesse, 2013; see Fig. 4.) has yet to be attempted in literacy research in a way that aligns with what is today known about biological and socio-ecological dynamics, but practitioner hints have been offered (e.g., Hrubby, 2011, 2019; Immordino-Yang et al., 2019; McCormick and Scherer, 2018).
4. *Naturalized epistemology.* As particularly evident over the past 70 years in the anglophone analytic tradition, philosophy can justify and constrain what natural science inquiry may bring to an understanding of language and thought (Bredo, 2016; Cunningham and Fitzgerald, 1996; Quine, 1951). We acknowledge that other Western philosophical traditions (i.e., continental European) have held more sway in educational research over the past few decades (e.g., Foucault, 1966; Heidegger, 1927/1962; Vygotsky, 1978), and that other traditions across the globe are equally worthy of review. We turn as a starting point to the post-positivist anglophone tradition, however, because of its relative emphasis on *empirical naturalism* over rationalist cohesion, *neo-pragmatist holism* rather than reductively determined categorical foundations, and the tacit acceptance, at least as a matter of *normative convention* on matters about which most philosophers (or educators, for that matter) lack technical expertise, of natural science understandings about phenomena presumed of *the greater than human world*, as in the neuro- and life sciences.
5. *A pivot in the anglophone philosophical tradition* during the mid-20th-century (e.g., Austin, 1962; Quine, 1951; Ryle, 1949; Sellars, 1957/1997; Wittgenstein, 1953) set the stage for this bounded relational-linguistic view of meaning and its purposes constrained by the need for communicative and communitarian engagement. Echoing motifs from the American Pragmatists and phenomenology, it addressed the central ethos of philosophy, “to understand how things in the broadest possible sense of the term hang together in the broadest possible sense of the term” (Sellars, 1963, p. 35), and framed subsequent philosophical investigations (e.g., Brandom, 1994; Lepore and Ludwig, 2005; McDowell, 1996; Millikan, 1984; Rorty, 1978, 1990). Furthermore, insights from the life and social sciences readily inform this tradition, as demonstrated by the diversity of views in current philosophy of mind, philosophy of biology, and neuro-philosophy (Chalmers, 1996; Cobb, 2020; Clark, 1996; Dennett,

1996, 2017; Kim, 2018; Millikan, 2005, 2017; Oyama, 2000; Seth, 2021). Given its continued attention to normative convention and science-informed analysis, we therefore hold recent anglophone epistemology indispensable for framing vigorous neuro- and life science informed literacy education theory that could be more easily translated for assimilation into the public schools and public discourse on education policy.

Finding a place for new realism in literacy research

What these three sectors share—developmental science, naturalized social science, and post-positivist epistemology is belief in, or at least an allowance for, an external, natural reality, which humans are not merely in (and in part responsible for) but are evolved, developed, and living forms of (Bronfenbrenner and Morris, 2007; Greenberg and Partridge, 2010; Lickliter and Honeycutt, 2015), and their indirect capacity for constructing understandings of that reality emergent of, and constrained by, bio-developmental, as well as social and cultural, processes for functioning in that reality (Gottlieb, 2001; Millikan, 1984, 2017). To observe that adaptive and developmental processes are best understood initially as biological is not a rationalization for yet more determinism, reductionism, and mechanism in educational theory, policy, and prescription (e.g., scripted programs, continuous assessments, leveling systems, developmental micromanagement). On the contrary, it is a call for understanding what biological systems, organisms, and human beings are: generative, dynamic, adaptively homeostatic, and opportunistically functional—change processes all that ultimately resist the deadening hand of authoritative prescription and prognostication (Fischer and Bidell, 1998).

It is not surprising that students treated to a curriculum that engages and advances their abilities through meaningful use (Alvermann, 2009; Pressley et al., 2001), seem to tap these bioecological dynamics. Naturalism can offer a complementary view to comprehensive and embodied constructs of classroom literacy practice, as it did for progressive educators a century ago who employed it to guide instructional design (Harris, 1964; Hruby et al., 2016). They recognized that people are not social, cultural, symbolic, linguistic, or ideo-political despite their biology, but because of it. Today, life science research lends further clarity to this insight: it does not follow that our nervous system is itself rationally or computationally symbolic in nature merely because it is presumed the cause of our conscious and cultural ability to be so. Cognitive computational metaphors ought to be used with caution as they are imposed categories of our own devising and not inherent to the greater-than-human world we are trying to understand. And from this it follows: we cannot transcend being emotionally embodied organisms (Marshall, 2015); there is no ghost in the machine to be taught or set free (Ryle, 1949/2009), and no mind-stuff to be uploaded to a matrix (Damasio, 1994; Seth, 2021). We are predisposed by nature to be nurtured by social belonging, approval, and meaningful identity.

Rationalist social science traditions aside, mainstream education's unease with biological idioms stems from its historical misuse to marginalize dispossess, or disenfranchise (Bazzul and Sykes, 2010; Biology and Gender Study Group, 1988; Davis, 1997; Lesko, 2012). This impetus seems still at work in educational policy efforts today, where low performers are segregated for specialized perpetuation of putative "disabilities" (Dever et al., 2016). And neurobiological rationales are still being offered up as justification (Yale Center for Dyslexia and Creativity, n.d.). But we hold this misunderstands human nature. The life sciences can be better used for more positive purposes, including appreciation for the necessary variance of individual uniqueness. We think this ought to be a strength, but, like psychology, neurobiology's emphasis on internal processes and singular distinctions can be mistaken as a validation of the individualism of modern Western culture and the troubled notion of the autonomous rational agent. Granted, Western individualism is lamented for its social atomism and anomie. The West's post-Enlightenment efforts toward democratic, literate, materialist, capitalist, and metropolitan systemics has been both its glory as well as the source of much critical discontent (Harari, 2015). Its pseudo-meritocratic classism refuses to see the elitism of the few as the source of the deprivation of the many (Piketty, 2017). And ecologically, it has become unrooted from and destructive to the earth, the natural world in whose play we remain (Beach et al., 2020).

But it is no more possible to have a vital society without agentive, intentional individuals than to have a complex living organism without agentive, intentional cells (notably neurons) or living cells without agentive, intentional proteins. The lower-order elements are organized into the higher-order entities that comprise their interrelation and are as actively crucial to the relationship within which they have emerged as the perpetuating functionality of the whole (Fischer and Bidell, 1998; Gottlieb, 2001; Lickliter and Honeycutt, 2015). Or as the self-contradicting truism would have it: the situation is not either/or but both/and: not nature or nurture but both, not structure or function but both, not agent or context but both, not any one level but all together (cf., Yaden et al., 2021). These binary distinctions are human constructs imposed to demarcate categories of aspect, not natural or observable causes. We cannot be social or cultural without also being biological. It is in our evolved nature to be nurtured by our caregivers and cultural surround (Immordino-Yang et al., 2019). And at a time when permutations of a persistent pandemic, ecological devastation, and global climate change confront us with both our intellectual fallibility and our physical mortality, accepting bioecological cohesion may serve as a first step toward responsible stewardship in education as in life. It would also be a fresh theoretical restart for literacy education research.

Models in science

In both the natural and social sciences, researchers sometimes build a model of a target of inquiry. There were famous model builders in history (e.g., Pythagoras, Leonardo, Kepler, Hobbes), but models became increasingly common in fields such as physics and economics during the first half of the twentieth century. Models now play an occasional role in scholarly research using qualitative methods and an extensive role in quantitative research across a wide range of disciplines (Friedman et al., 2008).

Models are problematic to define in part because their targets vary so much. Certainly, it is difficult to say anything specific about what a three-dimensional model of a DNA molecule, a formal model in political science based on game theory, the standard model of elementary particles, the Rasch psychometric model, and a cultural model of marriage in anthropology all have in common. There are also different kinds of models as well as subtypes of each (see Fig. 1).

Less elusive is what a model does: it provides a limited representation of the character, action, or appearance of its target. Both the remove and limits of a model may seem to be liabilities, but in fact they can be strengths. Because a model is not the target but representative of it, it can contain a mixture of features previously confirmed or well established and others inferred as possibly being the case. Because a model's representation is limited, inquiry based on a model is likely to have a closer focus than would an examination of the target. A model may also highlight an aspect of the target that would otherwise be missed or ignored.

Every model's representation of its target is limited, but a few kinds of limitations seem to elicit more criticism. Some models are idealized—for example, models based on rational-choice theory in economics or political science. Some models are analogical—for example, Neils Bohr's model of the atom depicting it as being like a solar system. By contrast, scale models—for example, those designed to test the feasibility of Elon Musk's hyperloop—appeal to common sense and seem to draw less criticism.

Fig. 1 Kinds of models with examples of subtypes.

A model not only represents a target of inquiry but generally has a meaningful relationship with one or more theories. The word, *model*, can be a synonym of *theory* for simple, narrow, or parsimonious theories that describe or depict a target (e.g., big bang theory/model) or when no theory yet exists that applies to a target. More often, a model is or could be part of an existing theory or has been deduced from one.

Literacy models must be built and interpreted in the context of what is known about reading and writing, how they are learned, and how they are taught. It would be a missed opportunity for the literacy field, though, if the meaning of the phrase, “what is known,” were taken as obvious or reduced to a debate about research methods. Knowledge itself has been studied for thousands of years. Epistemology is “the branch of philosophy that deals with the varieties, grounds, and validity of knowledge” (Brown, 1993, p. 838). Other entries in this encyclopedia volume appropriately address what is known about various aspects of literacy. The present chapter concentrates instead on the epistemology underlying or implicit in models of literacy.

Issues from epistemology

There are numerous issues regarding knowledge in epistemology, e.g., coherence, justification, objectivity. This article has been organized around three epistemological issues especially applicable to literacy models—reductionism, unobservables, and skepticism.

Reductionism as an epistemological issue

Disciplinary reductionism

If every object in nature consists of molecules, atoms, and subatomic particles, as almost all philosophers and researchers surely believe, why do we need any other scientific discipline besides physics? Since we have physics, why do we need chemistry or biology? Since we have the natural sciences, why do we need the social sciences? To put these questions as an epistemologist might, is what we claim to know specific to a discipline *reducible* to a more basic discipline, perhaps ultimately reducible to the definitions and laws of physics?

In the late nineteenth century, Émile Durkheim helped establish naturalistic social science, social inquiry conducted using the same research methods as the natural sciences (Durkheim, 1895/1982). At the same time, Durkheim defended the autonomy of academic sociology as a field by arguing for the existence of *social facts*, i.e., facts in society that constrain individuals, but which cannot be attributed to or explained by what individuals think, feel, or do (Durkheim, 1895/1982). Thus, Durkheim was an advocate for the unity of scientific methodology, but an opponent of the unity of science.

Starting in the 1920s, members of the philosophy of science movement known as logical positivism, later logical empiricism, likewise promoted unity in scientific methods, but also worked toward the unity of science itself. Rudolf Carnap [1891–1970] and Otto Neurath [1882–1945] argued that all sciences should adopt common principles of language. A parallel proposal for all scientific language was *operationalism*, first suggested by the physicist, Percy Bridgman (1927). Operationalism became the standard that scientific language be formulated or translated to consist only of formal and empirical statements. An empirical statement is one for which there exists a set of objective operations by which it may be observationally or experimentally tested, determining it to be confirmed (*verificationism*), rejected (*falsificationism*), or one or the other. Operationalism had its heyday during the era of behaviorism in psychology, economics, and education.

Early on, logical positivists/empiricists had been suspicious of theory, but Carl Hempel’s deductive-nomological model (e.g., Hempel and Oppenheim, 1948) was an approach to scientific theorizing that eschewed induction in favor of deduction and reduced causation to prediction. Research starts with a proposed or established law of nature that may explain the phenomenon

being investigated. It proceeds by describing the initial conditions for the phenomenon and then deducing from the law one or more hypotheses (predictions) about how the data to be collected will turn out. Hempel called his approach the “covering-law” model because for him science is the search for laws that cover (entail) the data to be collected to test them.

The deductive-nomological model became a strategy for those attempting to unify science through disciplinary reduction (e.g., Lewis, 1970; Oppenheim and Putnam, 1958). The strategy assumed that all laws (and lawlike generalizations), however well established, are hypothetical, like hypotheses before data collection in an individual study. As predictions of how data to be collected will turn out in a particular study can potentially be deduced from a law (and a statement of initial conditions), so each law of a less basic discipline was considered potentially deducible from those of a more basic discipline. Through many instances of such micro-reductions, the unity of science was eventually to be achieved (Oppenheim and Putnam, 1958).

The case made by logical positivists for having all scientific disciplines embrace common criteria of language was eventually refuted (Popper, 1965; Quine, 1951) as was operationalism (Hempel, 1966). The deductive-nomological model was substantially revised for several reasons. Despite David Hume’s argument against inductive reasoning (Hume, 1748/2007), most scientists and even most philosophers of science approve of it to some extent (Hacking, 2001; Rothchild, 2006). The covering law model cannot distinguish between generalizations that are lawlike from those that are accidentally the case and excludes kinds of scientific explanations accepted by many practicing scientists (Glennan, 2006). Much actual science does not conform itself to exceptionless laws, especially in historical sciences like biology (Rosenberg, 2016), geology, archeology, and anthropology. Finally, the unity of science failed as an epistemological project. The main reason was because each established discipline has ownership of facts more basic disciplines have been unable to explain satisfactorily (Rosenberg, 2016).

Explanatory reductionism

Complexity results from an object, process, or system having distinguishable causes or parts yet remaining a unified whole. Theoretical explanations are efforts to make the why and how of a phenomenon intelligible. Reductionism (or reductivism) is an attempt to explain the properties of a complex whole solely in terms of the properties of its causes or parts. In a regression model, for instance, a successful reduction is supported when the whole is accounted for by the weighted sum of its predictors and the model has been cross-validated.

Ockham’s razor—the many centuries old preference for simpler explanations of phenomena—has been an important motive for scientists to reduce theoretical complexity (Gauch, 2002). One advantage of parsimony (Ockham’s razor) is the methodological principle that theories (and models) with fewer hypothetical causes or components are more likely to be successful, because the more hypothetical entities a model includes, the more are available to fail an empirical test. Another advantage is that explanations with fewer assumptions simultaneously avoid the excesses of imaginative theorizing and overfitting models to the data collected.

A potential problem with explanatory reductionism, however, can arise if researchers exercise a preference for reduced explanations by ignoring facets of wholes, their complexity, or evidence supportive of more complex explanations (Dennett, 1995). Such zealous reductionism has sometimes been identified by its opponents as the “nothing-but reflex” (Davidson, 1980, p. 214), the nothing-but fallacy, or—most charmingly—nothing buttery. Wanting to defend what he calls “good reductionism” (p. 83) while acknowledging bad reductionism (nothing buttery), Dennett (1995) gives a new name, “greedy reductionism” (p. 83) to the latter. Nothing buttery (greedy reductionism) occurs when the whole is more (or less) than the sum of its parts/causes, but a reductive explanation of the whole is provided anyway.

Emergence instead of reduction

In contemporary model building, emergence is a hypothesis for why some reduced theories and models exhibit explanatory insufficiency. John Stuart Mill (1843) contrasted homopathic and heteropathic effects of a set of multiple causes. Later, G. H. Lewes (1875) renamed the same two kinds of effects *resultant* and *emergent*, respectively. Homopathic or resultant effects follow directly from the properties of their causes or equal their sum; heteropathic or emergent effects are not entirely predictable from the properties of their causes or are greater than their sum.

Emergence is manifest whenever a whole has qualities or effects that cannot be explained by the qualities or effects of its parts. For example, the behavior of an ant colony is an emergent property inexplicable from the properties of an individual ant. Some philosophers have used the term, *supervenience*, to label a condition of dependence on parts without causation.

There are two types of emergence, metaphysical and epistemological. For the British emergentists, Mill and others, and the more recent English philosopher, Roy Bhaskar (1986), many disciplines in the natural and social sciences exist as a reflection of the ontological stratification of nature. In principle, scientific disciplines can be ordered from most to least basic, consistent with the hierarchical order of the strata they study. For instance, physics is more basic than chemistry, which is more basic than biology, which is more basic than anthropology, because the layer of nature each science attends to supervenes on (depends on but is not fully explained by) more basic layers. If so, there are phenomena at each layer with characteristics beyond those resultant from causes operating at more basic strata.

Epistemological emergentists—the majority—have considered emergence to reflect the complexity of a phenomenon, to be the product of a complex web of interactions among its properties, parts, or causes. Chaos theory (Gleick, 2008) as applied across several disciplines can be seen as an example of explanation by epistemological emergence. The effects chaos theory models are assumed to result directly from their causes and initial conditions yet are extremely difficult to predict because of the complexity of their system—the quantity of causes, the quantity of their interactions of different orders (simple, 2-way, etc.)—and the complexity of the interaction of the whole system with initial conditions.

Literacy models and reductionism

Literacy is a cross-disciplinary field. Research on reading, writing, and literacy is published in literacy journals (e.g., *Reading Research Quarterly*), education journals not specific to literacy (e.g., *Journal of Educational Psychology*), journals associated with disciplines in arts and sciences (e.g., *Applied Linguistics*), journals focusing on technology or research methodology (e.g., *Behavior Research Methods*), and other academic journals (e.g., *Topics in Language Disorders*). The cross-disciplinary nature of literacy inquiry may be a key reason why models of literacy exist in such variety.

Even though the logical empiricist goal of unified science no longer animates many philosophers or scientists, there are specific disciplines today where claims to disciplinary autonomy are contested. Three of these disciplines—psychology, sociology, and cultural anthropology—have been directly or indirectly influential in literacy research. Paradoxically, psychology's integrity as a discipline is under threat of reduction today at the same time as it continues to pose a reductive threat to the disciplinary integrity of sociology and cultural anthropology. There are potential ramifications of these threats of disciplinary reduction for model building in literacy.

Will literacy models based on cognitive psychology be reduced to theories or models in neuroscience?

Psychology, including educational psychology, has been the social science within whose purview most research on literacy has been conducted. The quantity of psychologically oriented literacy research has greatly increased since the cognitive revolution. In recent decades, though it remains controversial, there seems to be wide acceptance of the conjecture that neuroscience will eventually replace psychology.

Hruby (2017) succinctly captures the challenge to psychology posed by neuroscience as it manifests itself in reading inquiry, "In approaching the neuroscience literatures on reading, most literacy scholars assume a ready connection with cognitive science. After all, is it not the case that the mind is in the brain?" (p. 192). Yet, distinctions from the philosophy of mind explain why literacy scholars should doubt an imminent transparent relationship between cognitive psychology and neuroscience.

Davidson (1970) appropriated the term, *supervenience*, to label his description of the mental being "in some sense dependent" (p. 214) on the physical without being reducible to it. A supervenient relationship has two dimensions, *dependence* and *irreducibility*. For Davidson, thoughts and actions are totally dependent on neural events in the brain, but irreducible to them.

Irreducibility of the psychological to the neurological is often argued by philosophers of mind using Putnam's (1967) *multiple realizability* thesis. This thesis asserts that two people may achieve similar perceptual, cognitive, or other psychological outcomes from different neurological states. Fodor's (1968) functionalism about mental properties also implied multiple realizability. In support of Putnam, Fodor, and their followers, Endicott (1993) reviewed findings from brain research that persons with brain injury or other conditions had developed alternative neural pathways or subprocesses to achieve specific psychological functions.

Hruby's (2017) account of the irreducibility dimension of the relationship applied to reading is an excellent summary of such insights, "perceptual and constructive abilities are possibly both predicated on a highly fluid neural architecture that allows for functional plasticity—or, in other words, that allows neurologically endowed organisms to wrap their nervous systems around their environment in highly individualized yet functional ways" (p. 208).

Whether the cognitive entirely depends on the physical, whether the cognitive is irreducible to the physical, and whether the cognitive encompasses emergent properties and powers all remain matters of contention in epistemology and the philosophy of mind. The persistence of these disagreements means models of literacy from neuroscience should be cautiously welcomed. Some will probably receive empirical support. Nevertheless, cognitive psychology still preserves its integrity and autonomy as a vibrant field despite decades of attack by disciplinary reductionists.

Are there social or cultural facts and phenomena in literacy?

Are the theories, models, and research findings of fields such as sociology and cultural anthropology (and political science and economics) reducible to psychology? Are the social and cultural dynamics operating in groups of people these fields study merely an aggregation of the psychologies of the individuals in those groups? Or do irreducible social and cultural forces and processes exist above and beyond individual psychologies that instead enable social scientists to predict or interpret the thoughts and actions of individuals? In short, are there social and cultural facts and meanings or are there only psychological facts and meanings? Competing answers to these questions come from long and continuing disputes between holists and individualists in epistemology and metaphysics.

Holists oppose disciplinary reductionism as well as explanatory reductionism by insisting that social or cultural phenomena have holistic explanations instead of or in addition to explanations based on the psychologies of the individuals who make up societies or live in cultures. As discussed earlier, Durkheim's (1895/1982) view of academic sociology included holism (the existence of social facts). The cultural anthropologist, Alfred Kroeber (1952), argued for the existence of cultural facts irreducible to facts about individuals living in a culture. The fields of sociology and cultural anthropology theorize that social and cultural wholes have social and cultural parts or causes. For many scholars in these fields, societies and cultures are social and cultural all the way down.

Individualists reject holistic explanations in favor of explanatory reductionism. They only acknowledge facts for groups as long as those facts are predictable or interpretable as the aggregated effects of the psychologies of individual people. Radical empiricists and positivists have seldom been holists because they consider emergent properties and effects to lack empirical legitimacy.

There appear to be social facts in literacy. For example, poverty has a clear impact on the social institution of schooling revealing itself in unequal outcomes in reading and writing achievement. There also appear to be cultural facts in literacy. For example, even though Whole Language conflates literacy with language, language is the product of biological evolution while literacy is the product of cultural evolution. The latter may depend on the former, but it is doubtful it can be reduced to it.

Implications of reductionism for literacy models

As of now, epistemology and the philosophy of social science leave us room to pursue literacy inquiry in ways consistent with the theories and methods of cognitive psychology, sociology, and cultural anthropology. Any disciplinary reductionism replacing these respective fields with neuroscience or psychology likely lies in the distant future if it ever comes to pass.

Explanatory reductionism is a more complicated matter. Although reductionism is a dirty word in some quarters, it performs an important function in scholarly inquiry. Even in interpretivist social science, where antireductionism is proudly owned, scholars often select a stance, lens, or theoretical framework to guide a study, presumably to avoid having to take every perspective one could take in a single inquiry. Reductionism has several possible implications for model selection and building in literacy:

- “Good reductionism” can aid builders of literacy models. Any literacy phenomenon can be modeled, whether it is a social, cultural, psychological, neurological, or other kind of phenomenon. For any literacy phenomenon, the representative nature of a model may constitute reductionism by design. The limits and remove of a literacy model can provide a literacy inquiry with needed focus and invite inferences.
- Ockham’s razor (the principle of parsimony) may serve the purposes of literacy inquiry. When two models explain a literacy phenomenon well, the one with fewer assumptions or hypothetical entities is more likely to withstand empirical scrutiny.
- Explanatory insufficiency regarding a literacy target of inquiry is a justification and motive for considering emergence, supervenience, or holism when newly modeling that target.

Unobservables as an epistemological issue

No one has ever seen a proton, let alone a quark, and physicists do not anticipate the development of an instrument that would allow either particle to be directly observed. Such *unobservables* have long presented a challenge to those with a radical empiricist epistemology.

The founders of modern empiricism, John Locke and David Hume, and their followers have largely held to the variously attributed axiom: “Nothing is in the intellect that was not first in the senses.” Locke’s (1690/1975) use of the metaphor, *tabula rasa* (blank slate), to describe the human mind in its original condition reflects his similar view that the source of all a person’s ideas is sense experience. For Locke, the senses comprise the classic five external ones plus reflection, internal awareness of one’s own mind in operation.

All empiricists share the belief that immediate sense experience constitutes the primary source and sanction for knowledge. However, it was probably Hume (1748/2007) who first formulated an empiricism so pure it merits the label, *radical*. Unlike Locke, Hume refused to accept any possibility of knowledge beyond what current observations afford. He argued against the possibility of knowing causation in science or everyday life. Later, Auguste Comte (1853/2009) coined the term *positivism* to describe his brand of radical empiricism. Comte restricted human knowledge to positive (i.e., certain) facts or laws arrived at empirically. He rejected all other claims to knowledge whether subjectively declared or the product of metaphysical argument. Radical empiricists and positivists since Hume and Comte have generally been uncomfortable with assertions about the existence or nature of anything that cannot be directly observed. The recent “constructive empiricist,” Van Fraassen (1980), is agnostic about the existence of unobservables and skeptical of all instruments used to indirectly observe them by their traces or effects.

Phenomena is Immanuel Kant’s (1787/1966) term for “object[s] or occurrence[s] perceived by the senses” (Flew, 1984, p. 266). What is experienced in hallucinations, dreams, etc. are not phenomena. In scientific realism, phenomena are different from data (Bogen and Woodward, 1988) because data are always from specific observations whereas phenomena are relatively consistent and stable across observations and observers. For example, reading comprehension data are usually answers to items on a specific test or task that purport to measure one or a set of instances of reading comprehension. Reading comprehension itself is a phenomenon that has been witnessed in many different ways through countless formal and informal observations made by innumerable observers across myriad times and places.

Some phenomena have the status of what metaphysicians call *natural kinds*. The chemical element, mercury, the animal species, moose, and the physical force, magnetism, are exemplars of natural kinds, “nature cut at its joints” as Plato [c. 428-c. 348 BCE] put it. Other phenomena remain contested in terms of whether they constitute a single category of objects or occurrences to which one may correctly refer using the name given to that category. Empiricists who believe in the existence of natural kinds await more data from more investigations before they are willing to confer that status on a phenomenon whose existence as a single category is disputed. Hacking (1999) has also argued for the existence of *social kinds*.

In the natural and social sciences today, phenomena rather than data are usually what models are constructed to explain or predict (Bogen and Woodward, 1988). Moreover, as the natural and social sciences have evolved into a search for causal mechanisms (Hedström and Ylikoski, 2010), many of the phenomena considered worthy of study are unobservable to some degree.

The existence and nature of unobservable phenomena are inferred. Their status as phenomena largely depends on the relative stability and consistency of their characteristics and facts about them supported by data from multiple investigations by multiple researchers.

Modeling unobservables

When a model of a target phenomenon is built, the model can represent both observable and unobservable objects, occurrences, processes, mechanisms, etc. Any unobservables in a model are the product of one or another kind of inferencing.

Inference

In his introduction to epistemology, Audi (1998) distinguishes between two kinds of beliefs. The first is directly based on sources of knowledge: perception, memory, consciousness, reason, or testimony. The second is based instead on other beliefs. He summarizes the value of the second kind of beliefs, "It is largely because we can inferentially build on what we already believe (or assume) that there is no limit to the richness and complexity of the ideas and theories we can construct" (p. 152).

According to Audi, inference is a kind of reasoning that enables us to acquire new beliefs and occasionally new knowledge, yet it is not a source of knowledge. If we lack knowledge, inference does us no good—there is nothing for it to build on, nothing for it to extend. When we do have knowledge, inference can increase and expand the knowledge we have. Deduction is the classic kind of logical inference that draws a necessary conclusion from one or more premises. Induction is the kind of probabilistic inference where a generalization is constructed after examining a set of particulars. Inference can also have an inventive potency based on the imagination.

Abduction

The founder of pragmatism, C. S. Peirce [1839–1914], added a third kind of reasoning to deduction and induction. *Abduction* is like induction because it is reasoning from instances (data). They differ in that, while induction makes a generalization about the data, abduction infers the best explanation (hypothesis) for the data. For example, after noticing a stack of unpaid bills on a desktop in your brother's home, you could induce that he owes a lot of money or abduce that he has been gambling excessively again.

Transcendental arguments

Transcendental arguments came to the fore in Kant's (1787/1966) epistemology. Some things are obviously the case (e.g., a particular event repeatedly occurs) and there are facts even most skeptics believe. A Kantian transcendental argument takes an obvious case or uncontroversial fact as its premise and deduces a necessary enabling condition for it from it.

During modeling in science, narrower and more contested transcendental arguments than Kant's can be made for an unobservable based on evidence, data, or prior research the model builder assumes and builds on. For instance, Brown and Smiley (1977) found that third grade participants retold 3.6 times as many of the most important quarter of the ideas than the least important quarter in unfamiliar fairy stories they had heard. A transcendental argument could be made by reasoning from this finding that the discourse structure of fairy tales (and possibly a broader range of texts) shapes listeners' (and possibly readers') sense of importance of the ideas in a text. This argument could lead a model builder to include an unobservable trait of sensitivity to such shaping in a model of text comprehension or an unobservable trait of shaping readers' sense of ideas' importance in a model of writing. Whenever a transcendental argument is used to justify the presence of a particular unobservable in a model, it is a type of inference.

Analogy

The British philosopher of science, Hesse (1963) argues that practicing scientists sometimes build a model of a target phenomenon based on an analogy with another well-understood phenomenon. She uses the familiar example of balls in motion on a billiard table as a model of gas particles in physical chemistry. For her, such an analogy is "positive" with respect to specific properties billiard balls and gas particles share (e.g., motion and impact), "negative" with respect to specific properties that distinguish them (e.g., billiard balls are hard and shiny; gas particles are not), and "neutral" with respect to any specific properties where it is currently uncertain whether billiard balls and gas particles share them. It is the "neutral" aspect of analogous models, Hesse (1963) contends, that scientists can fruitfully focus on to generate new hypotheses about a target (e.g., where another property of billiard balls in motion is theorized to also apply to gas particles). At the time of model building, it is one or more of these neutral properties with undetermined similarity to the target vis-à-vis the analog that are unobserved and inferred by analogy.

Implications of unobservables for literacy models

Many psychological, social, and cultural phenomena of interest to literacy scholars today cannot be directly observed (e.g., lexical access). Even when target literacy phenomena are observable, models of those phenomena frequently include unobservable components, processes, mechanisms, or causes. Thus, contemporary model building in literacy generally requires inferring of one kind or another. Epistemologies may be divulged by how researchers, theorists, and practitioners view such inferences. Radical empiricists resist inferring literacy unobservables or their characteristics and minimize inferences where they cannot avoid them altogether. Scientific realists work to make full use of inferences in their literacy models, limited only by the regimen of empirical testing. Social

constructionists are skeptical of inferential reasoning as an individual objective process and look instead for evidence of social or cultural reasons for the “inferences” people, including scientists, seem or claim to make. Unobservables have important implications for model selection and building in literacy:

- Unobservables constitute the vanguard of literacy inquiry. Modeling what is known or well-established in an area of literacy has summative value, but knowledge about literacy stands to grow when literacy model builders reach out into the dark, inquiring into unobservable phenomena or unobservable properties or parts of observable phenomena.
- Empirical testing of theories and models is necessary for scientific knowledge to increase. Once that is conceded, however, it must also be admitted it is not testing, but what is tested that advances understanding of the world, including the world of human experience. Inferences (deductions, inductions, abductions, transcendental arguments, and analogies) are tools by which risk takers posit the unobservables that often make empirical testing fruitful when it is. Those who desire to accelerate knowledge and understanding of literacy may do well to be wisely bold in their use of creativity and imagination to infer what can currently be seen in no other way.

Skepticism as an epistemological issue

A popular movie, *The Matrix*, showed us something out of a nightmare most of us never think about at other times. Epistemologists have long thought about such things. René Descartes [1596–1650] famously pondered the possibility that a powerful evil demon had deceived him into thinking of himself and his life as if they were real when they were an illusion. Putnam (1981) is credited with inspiring a similarly nightmarish notion in contemporary epistemology. What if I am just a brain in a vat being fed nutrients and artificial sensations from which my thought processes are constructing the world that seems real to me but isn’t? In epistemology, such scenarios have been exploited by some to defend a blanket skepticism about what the senses can tell us, but a more nuanced version of the same argument is frequently used today to support a related but lesser skepticism, one directed toward scientific theories and models. A formulation of this argument is that theories and models are *underdetermined* by data or evidence.

Underdetermination

In both the natural and social sciences, data are gained from human senses or amplifications of those senses. Data are often used to test hypotheses deduced from theories or models. What happens when data falsify a hypothesis? Philosophers and sociologists of science have noted that, rather than the hypothesis routinely being rejected, the theory, model, or methodology of testing the hypothesis is often tweaked instead to warrant the same hypothesis surviving to be tested again another day. Underdetermination of theory by data also pertains when data (including big data) are examined abductively to decide which existing theory or model best explains them. As with the evil-demon or brain-in-a-vat scenario, there is always another existing or imaginable theory or model besides the one being tested, fitted, or built that could also explain the data.

Some philosophers and researchers have been persuaded by the underdetermination of theory by data or evidence to adopt either a radically empiricist phenomenalism (all we can know are sensations, not what may lie behind them) or a postmodern relativism. The majority, however, have granted that theories and models do not achieve a consensus of acceptance, when they do, simply because the data/evidence could lead in no other direction. Rather, it has become broadly recognized that academic inquiry has other contexts and goals in addition to empiricism—historical, social, cultural, political, even esthetic and intuitive—that do and should influence which theories or models currently hold sway in a discipline.

Theory-ladenness

Another kind of skepticism is the thesis of the *theory-ladenness* of data based on Hanson’s (1958) assertion that all data and other evidence accumulated to test a theory or model are themselves theory-laden. When collecting data or other evidence to test a theory or model, the kind of data/evidence chosen, the way the observations are conducted, and the tolerances set to determine when an observation yields adequate information are themselves influenced by the theory or model being tested. How could it be otherwise? For instance, scientists would not have known to seek evidence for the curvature of space-time, or how to seek it, had they not first had Einstein’s general theory of relativity that predicted it.

Theory-ladenness has a more debatable and extreme implication, that the terminology of the hypothesis and the variable(s) observed have no meaning outside the theory or model being tested. Hence, there is no way to test theories or models without already assuming them to be correct. And might not researchers simply be finding what they expect to find? When theory-ladenness is felt to have this implication, it becomes an argument for relativism.

Theory-ladenness has become less of a damning critique in the natural and social sciences because its main thrust is to undermine the certainty of each test of a theory or model. Logical empiricism was still very much a force in 1958, but in the past six decades few philosophers of science and fewer scientists have been radical empiricists or positivists. Certainty is no longer the *sine qua non* in research to be obtained at the cost of everything else but sense data. Scientists and philosophers of science are more likely now to be scientific realists who consider science probabilistic and a process of successive approximation to knowledge, or pragmatists who are less committed to the truth of theories and models than to their usefulness.

Paradigm shifts

What has been interpreted by some as a third kind of skepticism toward scientific theories and models is Kuhn's (1970) thesis of *scientific revolutions* brought on by *paradigm shifts*. Kuhn's work was immensely important in the demise of logical empiricism. As discussed in the earlier section on reductionism, logical positivists/empiricists desired and foresaw the eventual unity of science. They understood the history of science to be (or believed it should be) a continuous evolution. During this process of incremental change, laws of nature are tested empirically, revised, and retested, and established laws in each discipline are eventually replaced by laws from a more basic discipline. Science marches on.

Kuhn's study of the history of science led him to paint a very different picture. In his account, science during a historical period adheres to a *paradigm*, a broad set of beliefs shared by scientists about the nature of things within which a set of scientific theories arises. These theories undergo empirical development and a set of scientific approaches and methods become normative. The purpose of the theories (and models, in more recent periods) and how they are evaluated is to help solve the problems presented by the ruling paradigm as important to solve. Rather than being evolutionary, scientific change as portrayed by Kuhn is revolutionary. The ruling paradigm is discarded when it no longer solves the most worrying problems of its period satisfactorily. It is replaced with a new paradigm that is incompatible and maybe incommensurable with its predecessor. As happened with Ptolemy's epicycles, the anomalies build up until a Copernicus (not always an individual) comes along to usher in a new paradigm. The subsequent change is revolutionary across the board including making what were facts during the reign of the earlier paradigm sometimes no longer be facts or no longer be relevant facts.

Kuhn's work (Horwich, 1993) still carries weight but more as a means of evaluating the current state of science in a discipline or specific area of inquiry than as a brand of skepticism. There are several reasons. The radical empiricism and positivism of the 1920s–1950s have long since ceased to matter much, so they require no opponent. More significantly, although the notion of a paradigm shift is regularly applied loosely to support relativism, Kuhn himself rejected such uses of his thesis. He acknowledged underdetermination of theories by evidence, but he also claimed to believe in objective science. And, though Kuhn drew anti-realist conclusions from the theory-ladenness of observations that was a tenet of his thesis, scientific realists also oppose the strict dichotomy between observations and theory assumed by radical empiricists/positivists.

A continuing contribution of Kuhn's view has been his account of what considerations enter into replacing a paradigm. He was careful to limit the role of social, cultural, political, and other non-scientific factors in scientific revolutions, but he gave them a place at the table, albeit an inferior one compared with empiricism.

Postmodernism

Compared with underdetermination, theory-ladenness, and paradigm shifts, *postmodernism* is a very different, much broader, and more powerful skepticism. It is not specifically directed toward theories or models or even science itself but targets the very possibility of any kind of knowledge. Postmodern (anti-)epistemology has dominated many discussions of knowledge in western Europe and North America since the late 1970s. Disenchantment with modernism had increased in the West until it reached a crescendo at that point. Writers from various fields had earlier begun discussions of knowledge that would lead them beyond modernist epistemologies. Among the more influential of these writers were Jacques Lacan (1966/1977), Louis Althusser (1965/1969), Jacques Derrida (1967/1976), Michel Foucault (1984), Jean Baudrillard (1973/1975), and Roland Barthes (1970/1974). When they and their followers were not being original, they often based their considerations of knowledge on the work of Friedrich Nietzsche [1844–1900] and Martin Heidegger [1889–1976].

Postmodernism is primarily a reaction against the claims to universality and the metanarratives dominating rationalism from Descartes through the structuralists. Postmodernists characterize modernism in a negative manner. To them modernism gave the world science, reason, Western civilization, Marxism, Freudianism, and so on. Each of these modernisms is a totalism because it organizes everything under and in subjection to whatever the universal principle is in that system. So, each of these systems tells a grand story that relates everything to everything else by using the system's universal principle as the theme. By making everything subordinate to a master narrative, each of these systems places some ideas and some groups of persons at the center and others at the periphery of the story being told. In short, according to the postmodernists, power—not truth—is the underlying principle behind all modernisms.

Modernism privileges some ideas and people; it marginalizes others. Each modernism, then, is just a perspective that forces knowledge to take a particular configuration. There is no one perspective that can be privileged above any other except by a sheer power grab.

An epistemological response to skepticism

Underdetermination, theory-ladenness, and paradigm shifts were first articulated in the philosophy of science, a branch of philosophy separate from epistemology but with direct links to it. The philosophy of science has philosophical jurisdiction over models of targets of inquiry in the natural and social sciences, but so does epistemology in a more general way that draws on a longer tradition.

In his introduction to epistemology, philosopher Audi (1998) discusses at length how one could respond to becoming aware of the possibility of a nightmare scenario like Descartes' evil demon or Putnam's brain in a vat. For Audi, it is the prospect he is hallucinating the vivid green field that seems to lie in front of him. Even though it is impossible for him not to believe it is there, he is aware the field could be a total delusion. How should a person, especially an epistemologist, think about truth and skepticism in the

light of such scenarios? For our purposes, the types of skepticism about models that follow from underdetermination, theory-ladenness, and paradigm shifts can be seen as presenting a lesser but parallel predicament to the ones confronted by Descartes, Putnam, Audi, and countless undergraduates drinking beer with friends after midnight.

For Audi, the straightforward response would simply be to doubt everything that can be doubted and then withhold judgment about the doubts. This response, however, will not do, at least not for most of us. Why not? Because Audi (1998, p. 283) thinks most people—and I would suggest most literacy researchers—have two competing “deep-seated desire[s].” One is “to believe as many significant truths as [we] can,” and the other is “to avoid believing falsehoods.” The first desire “pushes us in the direction of credulity ..., believing too much.” The second “pushes us toward ... skepticism ..., believing too little.”

On balance, each of Audi’s desires is for something good. The desire for truth motivates learning and inquiry. If we believe we know much more about nature, history, and each other compared to equally intelligent humans who lived, say, a thousand years ago, surely we can recognize desire for knowledge as a major reason for the progress. On the other hand, skepticism can motivate us not to be arrogant about what we think we know or have been taught, and not to be satisfied with explanatorily insufficient answers to important questions. In the case of underdetermination, theory-ladenness, and paradigm shifts—as we saw earlier in this section—we probably do well to take their brands of skepticism seriously without attributing to them more destructive power than they possess.

Postmodernism may be another issue altogether. Cunningham and Fitzgerald (1996) placed it in a cluster of epistemologies opposite to positivism/radical empiricism but sharing that cluster’s severe skepticism of how much can be known. Postmodernism’s thoroughgoing incredulity toward Knowledge and Truth is defended with a detailed critique of the modern project’s greatest sins, but it leaves us no prospect of any truths or knowledge except what is locally held and often contradictory across locales.

What then is to be made of postmodernism? The epistemologist, pragmatist, and critical theorist, Jürgen Habermas [1929–], has perhaps been postmodernism’s most important interlocutor and critic. For him, debate with postmodernists should focus on modern social practices and institutions instead of abstractions and theories far removed from the lives of ordinary people. Habermas has argued against the postmodernists’ totalism, their refusal to distinguish between modernism’s beneficial and oppressive practices, institutions, and ideals. With respect to empirical inquiry, Rosenberg (2016) judges that the philosophy of social science can neither take postmodernism seriously nor refute it other than by ignoring its arguments. It must simply be assumed to be false, although doing so does not confront what it may be saying to social scientists.

The postmodernist discourse most awkward to dismiss is its rehearsal of cases of rationalized oppression. No doubt it would be inconsistent with its critique for anyone to pick and choose from that critique, but it seems educators, not least literacy educators, ignore this facet of its critique at the peril of students everywhere.

Implications of skepticism for literacy models

Skepticism can be a valuable foil for serious inquiry in literacy. We need not bother doing research for those who already agree with our literacy model; if our inquiry succeeds, they stand to gain little knowledge from us. We need not do research for those so skeptical of our model or method that nothing we find could possibly change their minds. Instead, an ideal audience for any literacy inquiry is fair-minded skeptics who disagree with our model but can be persuaded. Fair-minded skeptics inspire rather than deter well-designed, conducted, and interpreted inquiry in literacy. Skepticism has possible implications for model selection and building in literacy:

- Literacy models are probably best chosen or constructed, tested, and interpreted with an audience of fair-minded skeptics in view.
- Three related brands of skepticism toward models and methods—underdetermination, theory-ladenness, paradigm shifts—merit due diligence from literacy researchers. We should rigorously look for anomalies in our data and value multiple inquiries conducted in varied ways into any unobservable.
- Literacy models for inquiry and education stand to strengthen public goods. Even so, those of us who build or employ them should be warned by history that some actions we take may have precedents in modern oppressions past, leading us to interrogate the social and cultural motives and consequences of our work.

Epistemology of two literacy models

This article ends by briefly examining the epistemology of two well-known literacy models. The models chosen contrast significantly on the three issues of reductionism, unobservables, and skepticism.

Simple view of reading (SVR)

The often-cited SVR is a “model of reading” (Gough and Tunmer, 1986, p. 6). The model’s chief and titular characteristic is simplicity: “that reading consists of only two components, decoding and linguistic comprehension” (Hoover and Gough, 1990, p. 150). Its theoretical parsimony is achieved by *nothing but* explanatory reductionism empowered by idealization of modeling.

Specifically, the SVR's explanation of reading beyond decoding is reduced to what can be measured with a listening comprehension test, an assessment requiring no reading. The SVR is an idealized model because it assumes that other empirically demonstrable aspects of reading besides decoding can safely be discounted:

The simple view does not claim that exactly the same procedures used in linguistic comprehension are employed in reading comprehension, for there are clear differences Each of these differences is likely to be reflected in processing differences. The simple view, however, argues that these differences are relatively minor in comparison to the great similarities between linguistic and reading comprehension.

Hoover and Gough (1990, p. 153).

The SVR model is epistemologically defended by directing skepticism against what are supposedly the main contrasting views: that decoding ability and therefore decoding instruction are unnecessary for reading English; and that the comprehension reading requires is different from understanding spoken language in important ways. These skepticisms are defended by citing studies finding that measures of decoding and listening comprehension together predict a measure of reading comprehension significantly and to a large extent (Hoover and Gough, 1990). Consistent with its explanatory reductionism and skepticism toward complexity, there are no unobservables inferred or modeled in the SVR. Direct measures of the three abilities modeled are assumed to provide valid and sufficient observations.

RAND reading comprehension heuristic

The RAND Reading Study Group (RRSG, 2002) presented a "formal definition of reading comprehension" (p. 4) illustrated by a "heuristic" (p. xiii). Their heuristic is a figure (p. xiv) that certainly looks like a model (see Fig. 2), but the RRSG treated it as an aid to "thinking about reading comprehension" (p. xiii) rather than a limited representation to be critiqued or tested.

The RAND heuristic could appropriately be labeled, "the complex view." It models reading comprehension as three elements—reader, text, activity—interrelating within a sociocultural context, but this is just the beginning. The thinking about reading comprehension the heuristic is to assist applies to three "domains ...: instruction, teacher preparation, and assessment" (p. xiii). The literacy research it is to foster "needs to be informed by ... multiple perspectives (including educational, cognitive, linguistic, sociolinguistic, discourse analytic, and cultural perspectives)" (p. 2), and to be research that "contributes to better theories of reading development, and produces knowledge that is useable in both classrooms and policymaking arenas" (p. xiii).

The only skepticism of consequence expressed was the RRSG's judgment that reading comprehension theories and models to date were not "adequately rich ... to provide a coherent foundation" (p. 2) for the research needed. However, some of the multiple perspectives endorsed by the RRSG (e.g., cognitive) could be consistent with inferring unobservables in literacy theories or models produced with the assistance of their heuristic, while other of the perspectives (e.g., sociolinguistic) could be suspicious of such inferences.

Fig. 2 RAND heuristic for thinking about reading comprehension. Reprinted from RAND Reading Study Group (2002).

Lessons

Models may sometimes embody a trade-off between explanatory reductionism and explanatory sufficiency, but neither the SVR's *nothing but* explanatory reductionism nor the RRSg's embrace of unprecedented complexity yields a sufficient explanation of reading comprehension as a phenomenon.

With its reliance on prediction and avoidance of causation, the SVR seems a vestige of logical empiricism's covering-law approach. As a result, the SVR has no answers for such practical questions as, "What cognitive mechanisms produce linguistic comprehension?" and "Does reading comprehension ability significantly influence listening comprehension ability?"

The RRSg sends us off in all directions at once to find the answers they claim are currently lacking. The SVR's model may be too simple, but it is difficult to imagine what would constitute a suitable model for the RRSg. The SVR is marked by skepticisms toward complexity, less idealized views, and unobservable constructs. The RAND heuristic includes little explicit skepticism, but the multiple perspectives the RRSg calls for in its research applications each has a core skepticism toward some or all of the other perspectives. Even research informed by multiple perspectives must choose skepticisms to endorse and ignore.

If the RAND heuristic was an attempt to bring about a paradigm shift in reading comprehension research, it appears to have failed. On the other hand, the SVR may be popular with some because it essentially undoes the paradigm shift known as the "cognitive revolution."

A model of literacy provides a limited representation of reading or writing, its components or causes, how it is learned, or how it is taught. Epistemology has relevance for understanding literacy models beyond research methods. Ultimately, literacy models are built in pursuit of knowledge and epistemology has the potential to inform all such endeavors.

Qualitative literacy and language research

Qualitative research has a long and rich history in literacy and language education. As detailed by Barone (2021), early qualitative (i.e., case study) research tended to be observational in which researchers detailed language and literacy activities, typically with their own children or family members (see e.g., Butler, 1975; White, 1956). Throughout the 1970s and 1980s, interest in qualitative research among scholars grew; however, acceptance among scholars was a slow and gradual process. As Reutzel and Mohr (2015) pointed out in their sample of 200 randomly selected studies spanning the 50 years of *Reading Research Quarterly* (RRQ), from 1965 to 1994, quantitative research was published at a rate of four to one, whereas, from 1995 to 2014, it was closer with a rate of 5 to 4. However, in a more nuanced analysis of publications across nine literacy journals from 2009 to 2014, Parsons et al. (2016) found that in RRQ, 58% of the studies were quantitative, 23% were qualitative, and 8% mixed methods and in JLR 30% of the studies were quantitative, 49% were qualitative, and 8% mixed methods.

In considering a historical perspective of qualitative research publications in language and literacy, it is important to note that the depth of qualitative research resulted in lengthier manuscripts, which often exceeded journal page limits, and as such, it was not uncommon for researchers to publish their work in books, allowing them to preserve the richness of their data. Despite the overall disparity in published qualitative research, the importance of qualitative research in understanding language and literacy is unequivocal. For example, the observational data from Clay (1967) is considered the impetus for research exploring the construct of emergent literacy. Dyson's (1997) case study research and Heath's (1983) ethnography remain still today as landmark studies into understanding family literacy. Emig's (1971) study of writing among twelfth-grade students, which she described as a "unique effort to utilize case studies for eliciting data about how students behave as they write" (p. 5), is considered the foundation in understanding writing as a *process*.

Looking back, the depth and insight into understanding language and literacy advanced through qualitative research is profound. Further, as qualitative research evolves, variations of, for example, ethnography or participatory action research, although not exactly or entirely new, can be characterized as leading-edge innovations, continuously moving the field forward. As we will show, largely due to researchers' increased attention to both learner and researcher identity and intersectionality, as well as to more layers of context (see e.g., Smagorinsky, 2018), the meaning of literacy itself has become more nuanced. What researchers are able to see is expanding as the ways they look expand, as their methodologies continue to stretch beyond assessing literacy practices to include learning more about who literacy learners are. The resulting insight into the lived experience and identity of the literacy learner also widens and deepens as the identity of the researcher and scope of inquiry increasingly intertwine—ultimately revealing an expanded view of the literacy learner. The direction of literacy and language studies toward genuine inclusivity seems to be progressing in accordance with an awareness that literacy cannot be truly understood, nor truly inclusive, unless the reality of the learner, from the learner's perspective, is at the heart of the research.

This deepened and broadened understanding of the nature of literacy, and of this expanded view of the literacy learner, seems natural in hindsight, given the nature of the iterations or delineated "moments" in qualitative research as presented by Denzin and Lincoln (2000, 2008, 2017) through the five editions of their esteemed *Sage Handbook of Qualitative Research* series. Importantly, although admittedly somewhat paradoxically, they do not characterize the progression of qualitative research as a typical evolution. That is, while there is a chronological nature to the moments they name and define, they are decidedly not linear, and the more recent "advancements" are not emphasized as "improvements." As Denzin and Lincoln (2000) describe, their historical moments "overlap and simultaneously operate in the present" (p. 2). This language is important because it emphasizes a sense of qualitative

research as maturing and developing, and as continuing to build on existing and established tradition—yet without the implication that earlier iterations were immature or underdeveloped. To illuminate this somewhat counterintuitive notion of development, we offer the theoretical framework of consciousness philosopher Wilber's (2000) integral metatheory, which also helps to explain how recent trends we notice in qualitative literacy and language research seem simultaneously new and old. This lens also offers a glimpse into how we may begin to imagine a nonlinear experience of the past, present, and future of qualitative research, akin to Denzin and Lincoln's notion of historical moments simultaneously operating in the present. Wilber's integral theory emerged from his meta-analysis of over a hundred human development theories, and what is most relevant here about developmental stage theories is that they are "growth" or "actualization" hierarchies, as opposed to "dominator" hierarchies. This means that each stage "transcends but includes" or "differentiates and integrates" the previous stages. New stages are qualitatively "better" only in the sense that they are more complex and thus more capable of insight, perspective, understanding, and inclusion, and so as such, they are simultaneously able to see the limitations of previous stages *and* also deeply cherish them. In keeping with Denzin and Lincoln's contention, there is the inherent belief that lower or previous stages, offered here as parallels to the qualitative moments and their methodologies and offerings, are not "wrong," but are only partial:

The reason that earlier wisdoms need to be remembered is that in a healthy development each stage "transcends but includes" its predecessor: it goes beyond or brings forth new and emergent truths not previously found, but it also needs to include and embrace the important previous truths themselves, at pain of developmental dysfunction and disharmony.

Wilber (2017, p. 14).

To a certain extent, such a view also minimizes the relevance of distinctions between past, present, and future, while also serving to open epistemological possibilities for both prediction and hopeful aspirations for where qualitative research may continue to lead. Indeed, in their third edition (2008), Denzin and Lincoln speculate that qualitative research might be "undergoing a stunning compression of time, of moments" (p. 541). We cannot help but notice how we are living the very predictions and calls presented by Denzin and Lincoln, as well as their caveat that the revisiting of earlier moments "operates at different levels of abstractions" (2000, p. 1050)—a claim also made clearer by thinking in terms of growth hierarchies. All of the moments Denzin and Lincoln identified are still with us, and where they ended in their most recent edition is both where we are and where we still seem to be going.

Put another, more specific, way, there is a sense that each moment was born of a felt need to improve upon what preceded. For instance (though this is an oversimplification), the "traditional period" of the first half of the twentieth century blossomed into the "blurred genres" of 1970–1986, when "qualitative researchers had a full complement of paradigms, methods, and strategies to employ in their research" (Denzin and Lincoln, 2000, p. 15). The boundaries between social science and the humanities blurred, and the researcher's increased presence in the interpretive text, along with a concern that too much blurring and the narrative turn would discredit the legitimacy of qualitative research, gave way to the "crisis of representation," which was answered by the "post-modern period of experimental ethnographic writing" from the late 1980s through 1995. When trying to describe the then "future" on the horizon, which they labeled "the future (now -)," Denzin and Lincoln began using the word "sacred" rather liberally, both envisioning and calling for a future "concerned with moral discourse, with the development of sacred textualities ... sites for critical conversations about democracy, race, gender, class, nation-states, globalization, freedom, and community" (2000, p. 3). Moreover, their emphasis on qualitative research as defined by the interconnectedness of the "generic activities" of theory, method, analysis, ontology, epistemology, and epistemology that individual researchers uniquely bring to life, while another "not new" idea, was a prescient nod to the decreasing willingness of researchers to maintain boundaries between these components. As we will show, the onto-epistemological stances that we see so prevalent of late reveals an underlying assumption that ways of and beliefs about knowledge and knowing cannot be neatly parsed out from those about reality. That is, the nature of reality and of knowing cannot be considered separately, and we find this belief widely evident as insights from quantum physics have prominently arrived on the qualitative research landscape (Monk-Turner, 2020; Sailors et al., 2018). As Barad (2003) explains:

The primary epistemological unit is not independent objects with inherent boundaries and properties but rather phenomena. ... phenomena do not merely mark the epistemological inseparability of "observer" and "observed;" rather, phenomena are the ontological inseparability of agentially intra-acting "components." ... the "knower" does not stand in a relation of absolute externality to the natural world being investigated—there is no such exterior observational point. We are not outside observers of the world. Nor are we simply located at particular places in the world; rather, we are part of the world in its ongoing intra-activity (p. 815).

Barad's depiction, we suggest, resonates with Denzin and Lincoln's notions of sacredness, their imagined future of inquiry that "erases traditional distinctions among epistemology, ethics, and esthetics ... seek[ing] to ground the self in a sense of the sacred ... to illuminate the unity of the self in its relationship to the reconstructed, moral, and sacred natural world ... seek[ing] a sacred epistemology that recognizes the essential ethical unity of mind and nature" (2000, p. 1052). Together, these lines of thinking make the onto-epistemological framework that we utilize here.

Notably, in their third edition (2008), Lincoln and Denzin redubbed their "the future (now-)/out of the past" seventh moment into the "methodologically contested present" and their new imagined future became their projected eighth and ninth moments of "qualitative research in/and the fractured future." They revised an assertion from an earlier edition regarding qualitative research's coming of age, noting that it actually "had merely reached a zesty and robustly athletic late youth," and they predicted that the

genuine coming of age will be marked by a forthcoming maturation into “a new praxis that is deeply responsive and accountable to those it serves” (pp. 549–550). Similarly, and most recently, in their fifth edition (2017), they note an important shift of critical stances in interpretation and representation: that, historically, “critical perspectives were, in some cases, simply a companion, not a conjoined voice. That has changed” (p. 924). We find the final lines of their epilogue not only a compelling call for but an apt description of what we see in contemporary literacy research as situated in our current social and political landscape:

Far from being some imaginary end point, we are in fact at the edge of a new colonialism, a new era, one that we did not fully choose, and one that we must begin to understand more fully than we have to this point. The only meaningful method for that understanding is a refashioned, refunctioned, repurposed imaginary for ethnography and ethnographers. And that is yet to be invented (p. 927).

Considered in the context of their arc of their looking back and forward across moments, we interpret this new imaginary and invention in the established spirit of continuing the “re”-visiting, and at unprecedented new “levels of abstraction” (2000, p. 1050). Nestled in this interpretation, we began our inquiry with the consideration of what moments are featured in current qualitative language and literacy research. We chose to focus this analysis on qualitative research published in US based journals in the past 5 years (2015–2020) in the *Journal of Literacy Research (JLR)* and *Research in the Teaching of English (RTE)*, as these journals are highly regarded, have the highest prevalence rates of published qualitative studies, and span a range of age groups and topics. The qualitative studies published during this time frame encompassed a range of methodologies and were reflective of the many moments in qualitative research. However, what also became clear was the growing number of studies demonstrating Denzin and Lincoln’s premonition that we are arriving at where we are going. Thus, in our efforts to look forward, we turn the focus for this chapter to a consideration of how qualitative researchers seeking to understand language and literacy phenomena demonstrate clear commitments to social justice, equity and empowerment; dissolving and crossing boundaries; probing intersectionalities; and interrogating the intra-activity of people, materials, time, and place.

As anticipated, and in keeping with the onto-epistemological framework used in guiding this analysis, we discovered that the theoretical frames researchers used in guiding onto-epistemological language and literacy research overlapped, intra-acted, and intersected. The most prevalent theoretical frames we found in this body of research, which parallel Tierney’s (2018) “Dimensions of Global Meaning Making” were: (a) counter narratives, (b) intersectionality, and (c) “trans-” (e.g., translanguaging, transliteracies). There are a few caveats essential in noting to provide context to the discussion of these theoretical frames. First, and as with any theoretical shift, researchers’ portrayals of onto-epistemology varied, ranging along a continuum from identifying/labeling/defining to more integrated and holistic representations. Second, the theoretical frames, by the very nature of an onto-epistemological framework, are not discreet. Yet, for the purpose of providing a coherent discussion, we discuss each one separately.

Counter narratives

Solorzano and Yosso (2002) define counter narratives (or counter storytelling) “as a method of telling the stories of those people whose experiences are not often told (i.e., those on the margins of society)” (p. 32). These narratives challenge the status quo by countering the dominant discourse and exposing and confronting racial privilege. Solorzano and Yosso delineate three specific types of counter narrative: (a) personal stories, (b) stories of others, and (c) composite stories.

Personal stories

In Baker-Bell’s (2017) personal counter narrative, she situated her 1st years in academia within her life experiences from childhood as a young black into adulthood as a black woman. Through the complexity of the strong black woman myth, Baker-Bell’s narrative describes how she “existed, resisted, and persisted during ... on the tenure track as a Black woman and emerging language and literacy scholar with a family” (p. 540). Jang (2017) also used a personal counter narrative to describe how, in his 1st years in academia, his encounters with deficit-based racialized discourse provided insight into how he positioned himself and how he was positioned by others; recognizing how such positioning was both detrimental and potentially advantageous. In teaching literacy, he was questioned “how can you teach us this course even though you are a non-native speaker? It’s all about decoding stuff” (p. 571); however, as a quantitative researcher he was respected. These counter narrative personal stories highlight the importance of understanding the researcher as we seek to better understand language and literacy.

Stories of others

In a 3-year ethnographic study, San Pedro’s (2015) counter narrative challenged the dominant discourse through his depiction of how the use of silence with Native American students was a means for the students to enact their agency. As San Pedro noted, “storying allowed us—participants and me—space to share our developing understandings of the intentionality of silence” (p. 137). Using a life history interview approach, Vieira’s (2016) counter narrative illuminated how the life experiences among migrant families shape their literacy use upon returning to their homeland residence. Grounded in the theoretical framework of sociomateriality, Vieira captured how literacy cannot be separated from economics, politics, time, nor space.

Furthermore, in two interconnected ethnographic case studies, Ellison and Solomon (2019) used a counter-storytelling framework to analyze the ways two African American children and one parent talk about digital literacies, race, and the digital divide. By

doing so, the researchers highlighted how moving away from the deficit thinking of the digital divide provided the space for understanding, “the ways African American children are using technologies-not as passive content consumers, but as active and creative content producers whose activities support and transform their own learning” (p. 238). And finally, [Lam et al. \(2021\)](#) used a multi-modal storytelling lens to study the construction of scale. Through their research, they “contribute to literacy learning and teaching that support young people in bringing their knowledge, experiences, and narrative resources to engage with societal structures. ... In this way, we think that media production offers opportunity for students to document and mobilize their own and their communities’ language and semiotic repertoires, and to analyze and orchestrate them in relation to other community and institutional voices to extend important conversations in society” (p. 362).

Composite stories

In a composite narrative, researchers use data to create characters and then place these characters in social and political contexts. Using a version of this approach, [Tolliver \(2020\)](#) constructed a counter narrative of Avenae’J though integrating the work from her short story, fieldnotes from observations of writer’s workshop, and interviews. Tolliver included Avenae’J’s story in its entirety. In reflecting on her story, Avenae’J explained:

When I was writing this story, my problem was that people, a lot of African Americans, were being killed and then not being represented because of color. There is a lot of African American women who are not being represented even if they’re being killed just because they are African American. ... I thought that in 10 years, if it did not stop, there was going to be more killings ... In 50 years, there would be a civil war between different groups. Multiple groups fighting against multiple groups (p. 522).

Avenae’J further explained the main character in the story, “Avenae’J is one of those people ... well, she’s a lot like me. I just took myself and put me in my own story. That is why her name is my name. I like to put myself into my writing because it makes me feel better ... not feel better, but it makes me understand the story more” (p. 523). Through counter narratives, we hear the untold and unheard stories, and as Tolliver concluded, “We tell our stories to envision worlds beyond the one we currently inhabit and to imagine more just futures. Through Avenae’J story, she shared her understandings and experiences of the world, and she provided readers an opportunity to listen and respond” (p. 526).

Intersectionality

Building on Crenshaw’s original conception of intersectionality as it applied to law, [Cho et al. \(2013\)](#) delineate how this construct is now used widely across numerous disciplines. They conclude by locating research in intersectionality as follows:

By focusing on structures of power that constitute subjects in particular sociopolitical formations, we locate intersectional dynamics in social space and time. This does not mean, however, that subjects are simply structural positions. It does mean that debates in intersectional studies will circulate less around categories and identities and more around how those categories and identities and their specific content are contingent on the dynamics under study or of political interest (p. 807).

[Sciurba’s \(2017\)](#) study of male readers of color, illuminates how intersectionality provides fluidity and depth in understanding reader response and identity. The high level of engagement the participants demonstrated in two very different types of text captured the variability in the ways they connected to these texts. At times the boys connected the texts to their own lives as with the texts serving as windows and/or mirrors or the boys just found other relevant connections. “Even if the boys did not see their current worlds reflected while reading the stories, they became ‘active authors’ of their own possible worlds or found value in learning about how their current and future worlds (might) evolve. Their ‘personal and social identities’ proved to be multifaceted, too—influenced not only by race/ethnicity and gender but by popular culture” (p. 389). Similarly, [Compton-Lilly et al. \(2017\)](#) demonstrate how intersectionality offers a more nuanced understanding of literacy and identity among young children. Building on the premise that identities are fluid, contextual, and social, Compton-Lilly et al. demonstrate how intersectionality exposes how young children’s identity negotiations “are deeply situated in social contexts that bring long histories of privilege” (p. 122). In terms of early literacy

... intersectionality matters. It reveals how the teaching of reading, writing, and other literacy practices is intricately interwoven with networks of self that extend beyond classrooms. For young children, this intersectionality is not merely about the intersectional networks of race, gender, social class, and language the children bring but also about how those ways of being are taken up, valued, and negotiated by both the children and the people they encounter. As children negotiate networks of self, adults must not only support children in negotiating this multiplicity but also view children as active and invested individuals who have the capacity to contribute to their own becomings (p. 135).

Through a framework that included gender, masculinity, language, discourse, and identities, [Qin \(2018\)](#) explored the language learning experiences of Tiger, a 15-year-old student originally from Taiwan.

Tiger's masculinity performances were deeply intertwined with his participation in the classroom interactions, got entangled with the process of language learning and relations of power, and complicated his language learning experience and trajectory, leading to him being labeled as a "not serious" and "problem" student. While his masculinity performances took up and reinforced the dominant discourses of doing masculinity, his way of doing funny challenged the routinized language instruction, the censoring pedagogy, and the colonizing "good learner" discourses imposed and legitimized by the institutional power of the school (p. 449).

Translanguaging, transliteracies and transnational

Stornaiuolo et al. (2017) developed a framework to offer a conceptual understanding of transliteracy in a global world. Drawing from the work of scholars across many disciplines, the prefix trans is often thought of as across or beyond of through. In relation to literacy, Stornaiuolo, et al. appreciate the ambiguity it adds as "—it leaves unspecified who or what is moving or being moved, and how. Without assuming the relationships between what moves in advance, a trans-focus spotlights the activity of creating, maintaining, and disassembling associations across spacetimes" (p. 73). In further theorizing transliteracy, they suggest the following:

We propose that affixing trans- to the root word literacies foregrounds particular dimensions of literacies that can prove generative for research and analysis as literacies are lived, explored, described, analyzed, and enacted in critical and creative social practices, situated within and across ideological systems and characterized by the movements and interactions of people and things. This framing rests on foundational sociocultural claims that literacies are not located solely within individuals' minds (i.e., as skills or abilities) but are developed and constructed in distributed social practices constitutive of all human activity.

Duran (2017) used transliteracies to deepen our understanding of audience awareness among young writers. The students participated in a writing workshop approach modified to focus on audience awareness. Each unit incorporated different genres of writing and a range of audiences (e.g., family, peers, community member). At the start of the year, operating from a deficit model based on test-scores, except for one student, all students were positioned as at-risk learners. However, the teacher's willingness to embrace a transliteracies perspective provided a framework to shift from a deficit perspective to a gifted one. As evidenced in the findings, "students displayed rhetorical astuteness as they chose and combined language(s) in nuanced ways" (p. 107).

In a think aloud study using a transliteracies framework, Garcia and Godina (2017) explored the strategies fourth-grade, bilingual students used in interpreting and discussing Spanish and English texts. Findings indicated that the students varied in their cognitive approaches; however, they were similar in language approaches. That is, the students frequently used one language to explain their reading in the other language and they rarely used cognates, and they displayed a wider range of strategies than student who speak only one language. The findings from this study provide compelling evidence that translanguaging "appears to characterize how the fourth graders in our study approached, discussed, and interpreted texts, especially if we use Daniel and Pacheco's (2016) definition of translanguaging as "moving across languages and registers of speech to make meaning" (p. 653)" (p. 295).

In a critical ethnographic case study, Rounsaville (2017) used translanguaging to capture writing across a lifespan. Through this perspective, Rounsaville was able to demonstrate that writing is more than text-type; rather writing across one's lifetime encompasses how genres are inherited, created, and moved and are inclusive of transnational links. As Rounsaville explains:

I found that Clara built her repertoire over time, generations, and contexts. Stated attachments and assigned significances indexed her transnational aims and concerns, which accrued as patterned social actions—as defined by Clara—guiding and governing how she moved genre across time, space, generation, and text-type. ... As Clara's case has shown, tracing the actions assigned to texts from an emic perspective—through the method of genre mapping—enabled an expansive look at how "here" and "there" were coordinated. Specifically, findings revealed how orientations to literacy inherited and made in one childhood persisted over time and across contexts and were handed down to the children of other migrant families. Social actions assigned to writing, accrued through childhood and young adult writing, became a consequential bridge across difference for Clara's work as a bilingual literacy educator (p. 334).

de los Ríos and Seltzer (2017) provide additional compelling evidence that emphasize the importance of translanguaging pedagogy to improve writing instruction. de los Ríos and Seltzer center their argument on how this perspective shifts the characterization of bilingual learners from being marginalized and often characterized as at-risk to one that recognizing the strengths in their linguistic abilities, providing opportunities, and creating the space needed to situate their linguistic and cultural abilities at the core of their learning. To truly capitalize on this approach, de los Ríos and Seltzer focused the topic of the writing on challenging coloniality. Building on the importance of intersectionality, the students engaged in positive writing experiences, and were able to "imagine themselves as decolonial subjects whose futures will be on their own terms. A decolonial imaginary means moving past simply 'allowing' students to draw on their everyday language practices and instead centers instruction and curricula around who and where students are as historically colonized and racialized subjects" (p. 70).

In a two-part study focused on improving instructional practices, Stewart and Hansen-Thomas (2016) sought first to identify what transnational experiences were evident in a participant's life and literacies, and then to explore how the student responded to instructional practices that leveraged her transnational life and literacies through translanguaging. Their findings led them to conclude that, "Sanctioning a space for translanguaging as part of a 'multilingual awareness pedagogy' enables emergent bilingual

transnational students to engage in greater creativity and criticality as they engage their full linguistic repertoires. Translanguaging facilitates students' use of higher-order thinking to make decisions and evaluate all linguistic options available to them in their writing" (p. 467).

Conclusion

Using an onto-epistemological framework, qualitative researchers deepen our understanding of language and literacy through research that enacts many of Tierney's (2018) "Dimensions of Global Meaning Making." Through Counter Narratives researchers interrupted existing frames through their stories that disrupted the colonized status quo. Using an intersectionality framework, researchers interrogated truth/post-truth by challenging orthodox positionalities with multifaceted and complex depictions of identities and positionality. Through a focus on translanguaging, transliteracies and transnationalism, researchers "decolonized spaces," as they disrupted dominant political and cultural spaces.

Through their qualitative research, these scholars aimed to "disrupt the normative—an imaginary that challenges the colonized status quo" (Tierney, 2018, p. 407) as they deconstructed the researcher/researched dichotomies and afford readers the opportunity to see language and literacy through learners whose stories are often untold. Drawing on Yeats' poem *Among School Children*, in which Yeats asks, "How can we know the dancer from the dance," Bloome and Green (2015) extend the imagery of the inseparability of the dancer and the dance to broaden our understanding of literacy and literacy research. They suggest, "Literacy cannot be separated from what people are doing, how they are doing it, when, where, under what conditions and with whom they are doing it; metaphorically, there is no separation of the dancer from the dance" (p. 20).

The deconstruction of binary thinking, of course, is another not-new idea. But what is new is the evolving, subtly different onto-epistemological stance that can hold contradiction or inconclusively as not necessarily or exclusively a temporary problem to eventually figure out, or as warranting some sort of gracious open-minded conciliatory gesture or relativistic "agree to disagree" accommodation on principle, but instead as a welcome and even satisfying indication of how much remains invisible, or yet unconsidered, or even in flux (This goes beyond acknowledging gaps or limitations in the research or identifying areas for future study. This also goes beyond the deconstruction that accompanies the postmodern failings of language to represent reality, though of course both are related and relevant). This evolving onto-epistemological stance, then, is not fueled by the drive for more information or refining of analysis to eventually reveal which of the seemingly contradictory pieces can be eliminated or otherwise solved; instead, this stance is eagerly patient to wait and see how, with more information and understanding, what may emerge is a way to comprehend how all of the information can make sense as part of the larger constellation. Lack of understanding becomes, paradoxically, part of the package of understanding. Not a void to be filled, that is, but a part of the landscape. Meanwhile, it nonetheless remains as important as ever to continue pursuing knowledge and understanding.

As Barad explained:

We do not obtain knowledge by standing outside of the world; we know because "we" are of the world. We are part of the world in its differential becoming. . . . Onto-epistemology—the study of practices of knowing in being—is probably a better way to think about the kind of understandings that are needed to come to terms with how specific intra-actions matter.

Barad (2003, p. 829).

Are we there yet? Perhaps not, but it seems language and literacy qualitative researchers are heading in that direction as the studies highlighted in this piece show promising signs of scholarship that advances "an approach to our worlds that challenges authoritarian circumstances that attempt to control knowledge narrowly or position other cultures as having fake or lesser forms of narrative" (Tierney, 2018, p. 413).

Introduction

The field of literacy is currently facing new, complex, and evolving problems (Beach & O'Brien, 2018; Moje et al., 2020). Conceptualizations of literacy are shifting, technologies are advancing, schooling is transforming to virtual and hybrid spaces, information and misinformation in the media and on social media is ever present, policies are being informed by outspoken parents and legislators or narrow conceptions of research rather than robust empirical investigation, and more. As a result—and rightfully so—the field of literacy is using new, complex, and evolving theories and methodologies to effectively address these big problems (Dillon & O'Brien, 2019; Duke and Mallette, 2021).

One concern noted in educational research generally and in literacy research specifically is the lack of theoretical articulation in published scholarship. For example, Parsons and colleagues (2016, 2020) analyzed 4305 articles published in 15 literacy journals across a 10-year period (2007–2016). They conducted a content analysis of topics studied, theoretical perspectives applied, research designs used, and data sources collected in these published articles. Pertinent to this chapter is the finding that a shocking 78% of articles did not explicitly present the theory or theories that informed the study. An important caveat is that the researchers used strict coding guidelines in identifying theoretical perspectives that required them to be explicitly presented. Nonetheless, this limited explicit presentation and application of theory in literacy research is concerning and serves as a call for researchers to clearly articulate and use theory in their research to ensure that it is informing research, theory, policy, and practice.

It must be stated that our concern with the explicit articulation of theories guiding literacy research work is not that we are using this feature as a proxy for being able to maintain a hierarchy of power that allows us to designate some work as “better” and other as “less than.” While we do believe that being grounded in theory is a prerequisite for research to be considered rigorous, we also believe that theory is continually at play in research work whether researchers acknowledge it or not. By identifying and explicating the language, assumptions, and delimitations—the theories—at work as a part of one’s inquiry, the serious researcher is laying bear for their audience what it is that undergirds the thought processes that have yielded the particular conclusions and insights they offer.

The truth of the matter is that each of us who conducts research within the field of literacy carries with us *some* set of working language, assumptions, and delimitations that are inextricably folded into our explorations. This truth exists whether we take time to make them legible for others or not and this truth exists whether or not the theory has a fancy or ‘official’ name to label it. In our estimation, the failure to explicitly identify these contributing factors, these framing theories, is evidence of another assumption: a research project that has not taken care to name the theoretical principles upon which it draws is making a (grossly erroneous) assumption that the foundational understandings of the world that it relies upon are normal and standard and universally accepted

and thus need not be clarified. We reject this notion and rather insist that researchers seeking to most justly impact individuals affected by their work must readily identify and describe the theories guiding their research endeavors.

This being said, educational research generally and literacy research particularly has experienced methodological tensions where historically quantitative and qualitative research has been perceived as conflicting approaches to inquiry. And these divides manifested in [Parsons et al.'s \(2016, 2020\)](#) content analysis of 15 literacy journals as well. That is, some journals published quantitative or qualitative research almost exclusively and seldom, if ever, published research from the other tradition. For this chapter, we present an analysis of the theoretical and methodological representation in publications of the Literacy Research Association (LRA), which, due to the LRA's sole focus on literacy research, we consider to be broadly representative of literacy research at large.

About LRA

LRA is a non-profit, international professional research organization with members "who share an interest in advancing literacy theory, research, and practice [it is] a community that engages in research and dialogue pertaining to literacy and related topics" ([Literacy Research Association, 2022](#)). A unique aspect particular to LRA is that it is decidedly focused on literacy research, unlike many literacy organizations that have a multi-lens focus on research, practice, and policy in literacy. As a stridently research-focused organization, LRA has been regarded as a leader in literacy research since its inception in the 1950s. Its annual conference and publications are viewed as *the* place for cutting edge research and theory development.

LRA publishes two journals: the *Journal of Literacy Research* (JLR) and *Literacy Research: Theory, Method, and Practice* (LR:TMP). JLR "is a peer-reviewed journal that has contributed to the advancement literacy and literacy education research for over 50 years" ([SAGE Journals, 2022](#)). It is a quarterly journal with a current impact factor of 2.918, demonstrating its significant contributions to the research literature. LR:TMP was formerly the *Yearbook of the Literacy Research Association*. All presenters at the LRA annual conference are invited to submit their presented research to the journal for blind peer review. Of the manuscripts that are submitted, only a portion (traditionally ~20%) are accepted for publication in LR:TMP. Both journals are highly selective and represent rigorous, timely, and significant scholarship in the field of literacy research.

This chapter reflects findings that emerged from a presidential charge from the Literacy Research Association to examine the range of epistemologies and methodologies represented within the organization over the previous 10-year time span. The authors were members of the ad hoc committee consisting of nine LRA members from diverse backgrounds and with diverse areas of interest and methodological expertise that was formed to meet this charge and were guided by the following questions:

1. To what extent are multiple methodologies and epistemologies represented across our conference and publications?
2. To what extent do our publications and conference address current problems in literacy via multiple methodologies and epistemologies simultaneously?

Although this charge and these questions prompted an investigation into recently published literacy research in LRA journals, we present them here simply to contextualize the catalyst for our undertaking. For this chapter, the authors considered the findings that emerged from the process, which aimed to capture literacy researchers' use of methodologies and epistemologies, to be contextualized within the current and rapidly changing literacy landscape. As such, this chapter takes a history of science ([Kuhn, 1962](#)) theoretical perspective to investigate how methodologies and epistemologies are driven by problems in literacy education and what that implies for the ways in which researchers approach research and the lenses that frame it. Additionally, we consider what [Reinking and Yaden \(2021\)](#) refer to as "productive theorizing" to speak to what we found as an absence of explicit theories in research.

Methods

This research used a mixed-method case study design. This investigation was mixed because it collected both quantitative and qualitative data. The bounded system ([Stake, 1995](#)) of this case study was the research methodologies and associated epistemologies and theories in LRA. This design is appropriate because mixed methods allowed us to collect a variety of data to examine research methodologies used within LRA from different perspectives and at various levels. Case study allows for a focused and in-depth exploration of phenomena within a bounded system ([Stake, 1995](#)).

Data collection and analysis

JLR content analysis (2007–2019)

A content analysis of the 2007–2019 volumes of *Journal of Literacy Research* was conducted. We included data from [Parsons et al. \(2020\)](#), which analyzed 2007–2016. In addition, we used the same procedures to gather data from three subsequent years: 2017, 2018, and 2019. The date range was selected to provide a view of literacy research trends over an expansive and recent time period. The peer-reviewed articles in each issue (a total of 209) were analyzed using a priori coding to document the following information for each article: (a) theoretical perspectives, (b) research design/methods, and (c) data sources.

The goal of this analysis was to explore the content of *JLR* over an extended recent period of time. Applying the a priori codes previously used by Parsons et al. (2016, 2020) allowed us to use and build upon the analysis of *JLR* already completed by he and his team in their study of 15 literacy journals. That is, *JLR* volumes from 2007 to 2016 were already coded, and our team applied the same coding to 2017–2019, thereby providing a broad analysis of *JLR*.

LR:TMP content analysis (2015–2019)

Similarly, a content analysis of the peer-reviewed articles from the 2015–2019 volumes of *Literacy Research: Theory, Methods, and Practice* were analyzed in each volume. The date range for this journal was conveniently selected because it represented the most recent five years of the journal at the time of analysis. A priori coding was used to code each article in that time frame (total of 80) the following: (a) theoretical perspectives, (b) research design/methods, and (c) data sources. We used the same a priori coding of *LR:TMP* articles as the previous *JLR* analysis to allow for consistency in coding journal articles to allow for comparison among LRA publications. The goal of this analysis was to examine trends over the previous five years in the research published in *LR:TMP*.

Self-reported epistemologies and methodologies in the conference submission system (2019 & 2020)

With the Research Committee's guidance, LRA leadership added questions about submitters' epistemologies and methodologies in the proposed sessions as a required component of the conference proposal submission system, asking them to choose from a menu of options or to select other and provide an unlisted category (see Appendix). The Research Committee collaboratively created the menu options to capture the epistemological, theoretical, and methodological approaches guiding research within LRA and the various contexts in which this research took place (e.g., grade level).

We opted not to use the same categories as those used in the journal article analysis because this was a new data source that allowed us to consolidate particular theories by the traditions under which they fall instead of documenting closely-related theories separately as was done in the analysis of journals. For example, in the journal analysis, which followed the procedures of Parsons et al. (2016, 2020), social practice theory and CHAT would have been coded separately. Researchers submitting proposals guided by social practice theory or CHAT to LRA would have categorized them as "sociocultural theories," which subsumed social practice theory and CHAT.

We collected these data in 2019 and 2020. The committee accumulated the totals for each of the codes to catalog the range of epistemologies and methodologies self-reported by researchers submitting proposals to the 2019 and 2020 conferences. Codes were analyzed by acceptances and rejections to see if particular epistemologies or methodologies were disproportionately accepted or rejected.

Results

JLR

Each of the 209 articles' theoretical frameworks was coded. The most frequently used were Not Specified (89), Multiple Theories (29), Sociocultural (24), and Other (18). The most common research designs were Qualitative (36), Case Study (34), Quantitative (30), and Nonempirical (22). The most frequently collected data sources were Observations (94), Interviews (90), Artifacts (77), Student Assessments (51), and Surveys/Questionnaires (32). The full results of this coding are presented in Table 1.

LR:TMP

The 80 articles' theoretical frameworks were coded. The most frequently used were Other (33), Multiple Theories (15), Not Specified (13), and Sociocultural (4). The most common research designs were Qualitative (15), Case Study/Collective Case Study (14), Other (12), Content Analysis (8), and Discourse Analysis (7). The most frequently collected data sources were Observations/Video Transcripts/Field notes (36), Interview Focus Groups (32), Artifacts (32), and Surveys/Questionnaires (13). The full results of this coding are presented in Table 2.

Self-reported epistemologies and methodologies

About 49% of the scholars who submitted proposals to the 2019 and 2020 LRA conferences reported that their epistemological stances fell within a constructivist paradigm. The next most commonly reported epistemology was critical/feminist/Marxist/post-structuralism (24%). Only 6% of respondents identified either post-positivist or positivist approaches as their epistemological stances. In terms of methodology, 26% of all submitted research used a qualitative case design. Interestingly, about 31% indicated that they used more than two research methods, which was coded as "mixed." A few epistemologies or methodologies appeared to be disproportionately accepted or rejected. Theoretical submissions were accepted less frequently (61%) than empirical proposals (73–79%, see Table 3) as were proposals that used Linguistics (46%) or Behaviorism (50%, see Table 5) as their theoretical perspectives. Tables 3–5 present the data from this analysis.

Discussion

Findings from this analysis of 209 articles from *JLR* (2007–2019), 80 articles from *LR:TMP* (2015–2019), and 1470 conference proposals (2019–2020) focused on (a) the extent of methodological and epistemological representation and (b) the extent to which LRA venues addressed current problems in literacy via those methodologies and epistemologies. We briefly consider underlying impetuses that ultimately inform the types of methodologies and epistemologies used in literacy research and their relevance in current social contexts. We also discuss what these findings might imply regarding future research.

Table 3 Frequencies of acceptance/rejection and percentage of acceptance of LRA conference proposals by research method 2019–2020.

Research method	Accepted (n)	Rejected (n)	Total	% Accepted
Formative experiments and design-based research	38	10	48	79.17
Literature review/research synthesis	67	25	92	72.83
Mixed methods	200	65	265	75.47
Qualitative	706	231	937	75.35
Quantitative	73	21	94	77.66
Theoretical (not data-based)	21	13	34	61.76

Methodologies used in LRA outlets included qualitative (e.g., social design methodologies, [Frankel et al., 2018](#); ethnography, [Buchholz, 2019](#)), quantitative (e.g., validation studies, [Gehsmann et al., 2017](#); correlational studies, [Lupo et al., 2017](#)) and mixed methods approaches (e.g., [O'Brien and Leighton, 2015](#)). Despite this documented diversity, most of the research presented at the LRA conference and published in LRA publications used qualitative methodologies and sociocultural and critical epistemologies. Though there were examples of both qualitative and quantitative research across our data set, qualitative studies outnumbered quantitative research at a ratio of roughly 10 to 1. The ratio of qualitative to mixed methods is approximately 10 to 3. The number of qualitative works far exceeded those with a quantitative design, creating an unequal distribution of methodologies represented across recent literacy research presented or published in LRA venues.

Table 4 Frequencies of acceptance/rejection and percentage of acceptance of LRA conference proposals by epistemology 2019–2020.

<i>Epistemology</i>	<i>Accepted (n)</i>	<i>Rejected (n)</i>	<i>Total</i>	<i>% Accepted</i>
Single category				
Constructivist	507	184	691	73.37

Multiple	338	113	451	74.94

Combinations of theoretical perspectives cited by 10 or more proposals were examined as their own categories. Combinations cited by fewer than 10 proposals were collapsed into the code "Multiple."

How should we interpret this methodological imbalance? As methods are driven by the research questions being asked, we suspect that some of the methodological trends highlighted by our analysis is a reflection of the pressing questions literacy scholars are posing and investigating as called for by current social contexts. It is not that quantitative methods have fallen out of favor or have been relegated by the literacy research community to an undesirable status. Rather, questions attempting to address the needs of our ever-changing world as related to societal power structures brought to the fore in particular by the COVID-19 global pandemic that onset in early 2020 along with the racial reckoning experienced in the US and across the globe in the summer of 2020 may be better explored via qualitative methods.

We do not see trends that indicate a collective movement toward a particular worldview (either domestically or internationally) as a field, and we see that as a positive outcome. Indeed, we encourage fellow literacy researchers to be open-minded about the potentialities of a range of methodologies and to continue to use methods that are theoretically grounded in perspectives that support rigorous and robust responses to timely and important questions about the world of literacy in its many forms. In particular, we encourage the application of new or combined methodologies and epistemologies that actively disrupt methodological

and epistemological binaries (e.g., [Dillon and O'Brien, 2019](#); [Purcell-Gates et al., 2016](#)), approaches we believe make space for new considerations poised to yield new insights.

We saw evidence of literacy researchers using multiple epistemological stances. For example, when considering the self-reported data from proposal submissions, it was common for researchers to report the employment of a variety of epistemologies based on the focus of a particular study. These observations lead us to ask additional questions about how theory is woven into literacy research work: How are researchers articulating their theoretically driven understandings of the literacy world, literacy research, and methods for forming continued understandings about literacy, and how are those articulations related to the ways they are (or are not) applying theory to their research efforts? These questions become particularly important when we use the collected data in an attempt to draw conclusions about the current field of literacy research and about where the field is headed. It also signals to us that as a field we must remain diligently nimble as we continue to be responsive to the literacy needs of the world, regardless of whether this will ultimately result in a singular or dominant orientation to literacy research.

The field of literacy research is tightly connected to the social and structural factors that provide the context within which the research occurs. We posit that expanding methodologies and epistemologies is not, then, an indication of its immaturity or underdevelopment ([Kuhn, 1962](#)), but rather its ability to flexibly contend with the ever-changing context. In relationship to current social movements that are encouraging more justice-oriented and equitably-driven understandings of the world at large, it is necessary that the focal points, methods, and theories underpinning literacy research are able to evolve in ways that allow it to address the most pressing needs within the world of literacy more specifically.

At the same time, we also acknowledge the pause that an inconsistent explicit application of theory in literacy research causes us, which others have also noted ([Anders et al., 2016](#)). In our analysis of *JLR*, for example, we found that 43% of the 209 articles did not explicitly articulate a theoretical framework. In *LR:TMP* 16% of articles did not clearly state the theoretical grounding. These findings are far better than what [Parsons et al. \(2020\)](#) found across 15 journals where 78% of articles did not explicitly name a theoretical perspective. Nonetheless, we find this omission of or unclear presentation of a theoretical framework problematic. As previously mentioned, at the core of the problem is the fact that working theories are framing any and all research efforts whether they are explicitly articulated or not. The candid presentation of the theories contributing to one's research work requires the researcher to seriously grapple with the assumptions about the world, themselves, learners, literacy and more that they are—subconsciously or intentionally—folding into their inquiry explorations. As the field of literacy research continues to advance, we call for literacy researchers to dedicate concentrated efforts to both consider and articulate theoretical foundations that drive their understandings and thus their methods for gathering data and the conclusions supported by the data collected.

We particularly concur with [Reinking and Yaden \(2021\)](#) that theorizing, particularly in literacy education, may be critical to productivity in research. They note, "For example, theories *about* [emphasis in original text] literacy can reveal hidden or ignored dimensions of literacy and established valued goals or a guiding moral conscience *for* [emphasis in original text] literacy research" (p. 385). As such, identifying theories about broader literacy topics may, in turn, forge stronger connections to classroom or field-based literacy practice. Again, our operational assumption is that, even if not explicitly stated or articulated, theories are certainly and persistently already in place. Given the diversity we have seen among methodologies and epistemologies utilized in the recent literacy research data analyzed here, we assume theories exist with a level of multiplicity that will continue to fuel a research field poised to provide significant and timely observations. But if we as a field are to be able to effectively address many of the big problems we outlined at the onset of this chapter, we must take on the task of thinking seriously enough about the theoretical assumptions we are embedding into our attempts to address those problems that we become adept at describing them with clarity and directness. We encourage explicitness in theory identification to draw stronger connections across research that may support stronger practice.

Conclusion

The current field of literacy—the problems it faces and the contexts in which it faces them—is incredibly complex. At the same time, the field of literacy is growing and expanding ([Beach & O'Brien, 2018](#); [Moje et al., 2020](#)). What literacy is and what it means to be literate is evolving more rapidly than ever before. Accordingly, researchers need multiple, diverse, integrated, and innovative theories and methodologies to study and understand these complexities ([Dillon & O'Brien, 2019](#); [Duke and Mallette, 2021](#)). Therefore, we believe that researchers continually learning and growing in their epistemological, theoretical, and methodological understandings will only serve to better the effort. Such respect for and use of diverse epistemologies and methodologies and continual development as scholars will serve to unite the field of literacy research, not divide it.

"Pikachu! Pikachu!" Crystal's voice could occasionally be heard calling out during one of my recent classroom research projects. While most of the other children participated in whole class discussions in the usual schooled way—raising hands and waiting to be called upon before responding—Crystal would occasionally jump into the flow, unbidden, squeakily inserting Pikachu from the sidelines. In these moments, Crystal was, as some would say, off-task.

What might have happened had this Pikachu-calling been recognized instead as an affective engagement with literacy with the potential to encourage and nurture Crystal's practice of literacy? In this entry, I explore this and two other moments of classroom literacy engagements that, when placed in conversation with post-structural (Deleuze and Guattari, 2004) and post-colonial (Wehliye, 2014) understandings of affect, offer a means for reconfiguring our understanding of young people's engagements with literacy.

Recognizing the importance of behavioral aspects of literacy, educational psychology has approached classroom literacy learning with constructs such as motivation and engagement for some time now (e.g., Guthrie and Klauda, 2014; Wigfield and Guthrie, 1996). Primarily interested in the relationship between reading comprehension, motivation, and engagement, the field accounts for cognitive aspects of literacy learning. However, based on a normative idea of what constitutes engagement with literacy, identifying singular measures of engagement, a cognitive-only approach offers limited scope for examining the multiple ways participation in literacy might occur. Sociocultural literacy scholars have also recognized the importance of motivation and engagement, shifting attention from the "reader-centric" focus of cognitive perspectives to an "activity-centric" approach to literacy (Pearson and Cervetti, 2015). While sociocultural literacy studies encompass a range of perspectives (e.g., Smagorinsky and O'Donnell-Allen, 1998; Snow and Verhoeven, 2001), Hruby et al. (2016) observe that sociocultural approaches to motivation and engagement commonly understand the "cause" and "effect" of engaged literacy to be located externally, situated in both historical and cultural contexts (p. 616). While both of these perspectives have provided important insights, neither of these approaches to engagement (cognitive internally focused or sociocultural externally focused) considers the role of the body and relationship—the individual as a relational member of the body collective, such as classrooms, communities, or families—in young people's engagement with literacy. The concept of affect addresses this matter, providing literacy educators and researchers with multiple avenues for recognizing and supporting young people's engagements with the textual production—a label I am using to refer to the multimodal texts (print, oral, visual, and embodied) with which young people engage.

Assemblage perspectives on affect

Affect is relational. It is aroused or sparked when bodies come into association with each other and thus affect theory needs to be understood within the larger theoretical realm of relational theories, such as affect theory, which commonly draw on the work of Gilles Deleuze and Felix Guattari. Assemblage perspectives view living beings as moving through the world as participants in heterogeneous groupings of human and more-than-human entities, otherwise referred to as assemblages (Deleuze and Guattari, 2004; DeLanda, 2006). Assemblages are constantly emerging, shifting, joining together, and breaking apart, as relations change, and participants enter and exit. They are non-hierarchical: that is, participation of humans is not automatically foregrounded in the functioning capacities of an assemblage. Thus, when an assemblage is mapped, people may be recognized as significant participants, but the participation of things such as signs, material objects, events, practices, and utterances must also be recognized.

Relations between the myriad more-than-human and human participants constitute the most important aspects of an assemblage's functioning. These relations are productive: they do things. While material things are the most easily recognizable of these productions, relations between participants also produce the immaterial, and affect is one of the most prominent of these immaterial productions. Thus, in a classroom literacy assemblage, we might easily recognize the inquiry projects, stories, notes made in

notebooks and on screens, text messages, or doodles produced by students on a page or whiteboard; however, attention to the immaterial requires us to notice the affect that is produced through students' relations with each other, their teachers, material items, and any other matter present or produced in the classroom assemblage.

Affect theory

Along with many theoretical bodies informed by assemblage perspectives, affect theory is grounded in work of 16th century Dutch philosopher, Baruch Spinoza, who is widely recognized within Western philosophy for disputing Descartes' mind-body dualism. Spinoza's writings emphasize bodily experience as an important aspect of knowing, inviting educators to consider ways people come to know, not only as epistemology (ways of knowing) but also as ontology (ways of being and doing). Spinoza famously identified affect as "the ability to affect and to be affected," highlighting affect's bi-directional force and flow but not necessarily defining it.

Over the last three decades, scholars in areas such as cultural studies, anthropology and sociology have begun to explore notions of affect, moving us toward a more precise and expansive conceptualization. [Massumi \(2004\)](#) identifies affect as "a prepersonal intensity corresponding to the passage from one experiential state of the body to another and implying an augmentation or diminution in that body's capacity to act" (p. xvi). [Gregg and Seigworth \(2010\)](#) add clarity to this notion of affect as an intensity, naming it as "those visceral forces beneath, alongside, or generally *other than* conscious knowing that can serve to drive us toward movement, thought, and ever-changing forms of relation" (p. 1). Following these scholars, I understand affect to be a form of embodied knowing, a visceral intensity that informs our immediate, practical actions and in the case of literacy, that which initiates the process of understanding and responding ([Lenters and McDermott, 2020](#)). Affect has also been described as a hunch or a visceral prompt ([Hickey-Moody, 2013](#)), an enchantment ([Bennett, 2001](#)), a feeling ([Leander and Ehret, 2019](#)), a vibration, rush, quiver, or surge ([Dutro, 2019](#)), a resonance ([Nxumalo and Villanueva, 2020](#)), and a stickiness ([Franklin-Phipps, 2020](#))—descriptive nouns that vividly animate and amplify the concept.

Affect is considered by many as distinct from emotion. While emotion is recognized as part of the meaning-making process, affect is considered to exceed consciousness ([Clough, 2007](#)), it is prepersonal ([Massumi, 2004](#)). Affect "precedes the articulations of language and thought. It is felt in the body before it is overlaid with meaning" ([Cannon, 2009](#), p. 74). In other words, affect comes before emotion, possibly only by seconds, but it is understood to be that which registers in the body before the mind processes it to form emotion. Although affect and cognition are understood, in practice, never to be fully separable ([Gregg and Seigworth, 2010](#)), this distinction between affect and emotion is useful for underscoring affect's role in social configurations, a role that can defy rational expectations for what might unfold as a body moves through its world.

Expanding conceptions of affect theory

The assemblages in which affect is produced are anything but straightforward. While much has been made of the idea that assemblages are comprised of human and more-than-human participants, critical race scholars remind us that thinking of "the human" as one generic category, belies the fact that in our social world, the experience of being human is not universal ([Weheliye, 2008](#); [Wynter, 2003](#); [Spillers, 1987](#)). This has implications for how affect is understood—in particular, the observation that not all affects are treated equally. Some people's affects count, and some do not.

Long-standing, institutionalized practices of racism, oppression and exclusion produce gendered and racialized violence that form the status quo in so many assemblages, making it difficult, if not impossible, for many to participate fully. [Weheliye \(2014\)](#) introduces the concept of *racializing assemblages* to draw to our attention these omnipresent systems. Weheliye (and others) argue that responding in racializing assemblages with confrontation only gives credence to that oppression, thereby further entrenching it ([Jocson and Dixon-Román, 2020](#); [Burton, 2017](#); [Weheliye, 2014](#)). Informed by critical race and queer theories, they advocate for ways of being and doing in assemblages that acknowledge affect "through fleshy humanness [as] a departure that survives and thrives in ... unorthodox ways" ([Burton, 2017](#), p. 35).

Classrooms and community organizations, all racializing assemblages, must allow "genres of being human" ([Wynter, 2003](#)) or in other words permit affective responses that sometimes push back on normative conceptions of what it means to "behave well" in a classroom. As [Snaza and Sandlin \(2017, p. 118\)](#) state, "classroom spaces often preserve the whiteness of educational institutions through the modulation and sanctioning of particular feelings." For instance, affective expressions of rage, despair, or defiance through spoken, embodied, and multimodal texts, particularly when associated with race or gender, are too frequently unwelcome in classrooms.

The concept of racializing assemblages thus underscores the notion that what a body does—its capacity to affect and be affected—is contoured by its relations with other bodies ([Deleuze and Guattari, 2004](#)) and what is typically considered acceptable behavior for those bodies ([Weheliye, 2014](#)). When applied to literacy learning, the concept of affect prompts educators to consider the "other than conscious" forces that work to enable, support, motivate and inspire literate engagements. Simultaneously, educators must consider what constrains the practice of literacy for some students, asking what is orienting and disorienting, transformative and normative, both in the classroom and elsewhere. In the next section, I explore some of these facets of affect in relation to literacy applications.

Affect as orienting and disorienting

Whether in school or in contexts other than school, young people make choices about the kinds of texts with which they will engage. These choices are not always rational or conscious (Jocsun and Dixon-Román, 2020; Lenters, 2016, 2018; Leander and Boldt, 2013). Something about a particular cartoon, film, comic, graphic novel, or picture book grabs their attention and holds it: perhaps the book appeals to their sense of humor; maybe it is aesthetically pleasing; possibly the story strikes a chord; or perhaps it is wildly popular with their friends and connects them to those friends in unspoken ways. Some texts invite a response in ways that seem highly organic, such as a text message or social media post in response to something posted by another, where the young person appears to barely pause before responding. The affect associated with such responses recognizable as response-driven by visceral, other than conscious knowing. In this way, affect orients young people toward literate engagement.

Affect may also be disorienting and can work in a couple of different ways. While affective feelings are so often what attract young people to a text, those feelings may just as easily be that which repels them. Even though they may not be able to name or identify, with words, exactly what is taking place, young people may form particular dislikes for certain types of texts. Thinking with affect about these disorientations directs educators to consider the assemblage in which distaste forms. Perhaps the student has formed feelings for a particular type of text (a literacy object) that relate to, for example, impossible classroom expectations around using that text, someone who was associated with that text at a particular moment, or how someone responded to a text the student produced. Often unspoken, feelings such as these can be intense and repel students from texts for reasons that have nothing to do with the text itself.

Affective disorientation can also have an upside. When texts unsettle, provoke or move students in certain ways, enlivening their senses with regard to a topic, an issue, a person, or a place, they are disoriented. As they are moved to think in new ways about things that might have been commonplace or stereotyped in their worlds, affective disorientation can open new possibilities and trajectories for them.

Affect as transformative and normative

The positive aspects of affective orientations and disorientations may prompt a tendency to focus on affect's transformative possibilities. While it is a key aspect of social and material literacy learning, a sole focus on transformation engenders a myopia that constrains attention to affect's potential in educational settings. Hemmings (2005), Dernikos et al. (2020, p. 9) state, "affect has the potential to be both transformative and normative." Hemmings contention is that "affective freedom," that is the ability for affect to radically alter an individual's subjectivity, ignores the fact that structural constraints exist and exert their influence on individuals and particular groups, and cannot be ignored in the pursuit of a research stance that is productive (as opposed to critical). When this is acknowledged, a glimpse of affect as both transformative and normative comes into view.

The call to move beyond the trap of critique for the sake of critique (Lather, 2016) that marks some applications of post-structural theory in literacy studies is valid and important. The productive, forward looking stance affect offers to those of us looking for generative practices in children's literacy education is invaluable, for it reminds us that following, for example, children's affective enchantment with particular literacy objects and practices provides important means for encouraging the transformative possibilities of alternate paths in children's literacy development. However, the cautionary note Hemmings provides is crucial in at least two ways: affect manifests in normative ways in the literacy classroom both through the educators' affective responses to children's textual productions and in the setting out of appropriate affective responses for children engaging with texts.

In classroom composing assemblages, a particular narrative around what are acceptable textual productions seems to pervade. Children who talk, sing, act, write, or draw about anything that either attends to or appears to promote violence (guns, fighting, war, anger) are often told these are inappropriate topics (e.g., Dyson, 2003). The child with productions of this sort might even be referred to a school psychologist. Not discounting the concerns that certain types of textual production engender for educators, these "inappropriate" topics are part of the fabric of many students' lives. Disallowing such productions or responding to them in particular ways can work to both disorient the student from literate engagements or worse, stigmatize the child within the classroom assemblage. Dutro (2019) provides an illustration of this as she relates the story of second-grade student, Malina. Malina's father, who had been incarcerated for several years, was a central figure in much of Malina's writing. Dutro writes,

In responding to her writing about her father, potential exists for fueling empathy, relationship, advocacy, and political commitment toward justice. But there is also the potential for pity, antipathy, fueling of deficit narratives, and political commitment toward injustice. White, heterosexual, gender normative, economically advantaged educators, like me, who benefit from privilege must be particularly vigilant against the latter response (pp. 386–387).

Educators' affective responses—pity, distaste, alarm—can function in normative ways to dictate what is appropriate, according to an unspoken ontology of privilege. Attuning to that affect is key to disrupting the classroom's racializing assemblage (Weheliye, 2014). Dutro (2019, p. 286) identifies this noticing as "a pause between sensation and language that allows us to question before we leap to certainty." By attending to and questioning the affect that precedes verbal and embodied responses to children's textual productions, educators can work toward building classroom assemblages that are transformative for all member children and not just those with whom we readily identify.

Normativity in educator affect may also be experienced by children in relation to their affective responses in literacy learning contexts. In recent years, classrooms have become more attentive to the critical need for providing literature in which all students

can see themselves; that is, diverse and culturally and linguistically responsive literature. However, particular notions of how literate engagement should be performed (e.g., [Luke, 1992](#)) can mean that diverse responses to literature are not always welcome. [Dernikos \(2020\)](#) identifies this force as *affective assimilation*. Educators may be more inclined to label a student as an engaged reader or writer when they are laser-focused on the text at hand. However, those whose impulse is to verbally or demonstratively share what excites or enrages them, as they engage with text, are often subjected to affective assimilation; that is, they are likely to receive a censorial shushing from their teacher or be labeled as disruptive. Again, by attuning to and validating such diverse or “fleshy” ([Burton, 2017](#); [Weheliye, 2014](#)) affective responses, educators can go a long way toward ensuring that affect becomes an expansive, rather than limiting, force in the classroom.

Affect should matter greatly to literacy educators—not just in effect-laden moments but also over the long-haul of a student’s educational trajectory. Just as attending to the transformative possibilities that registering affect can hold for young people’s literacy learning, research and pedagogy must be cognizant of the affective accretions that form over time. Following [Hemmings \(2005\)](#) discusses affective cycles of body-affect-emotion and argues that these cycles do not constitute singular events but rather “series of repeated moments” that form “an ongoing, incrementally altering chain—body—affect—emotion—affect—body—doubling back upon the body and influencing the individual’s capacity to act in the world” (p. 564). Put simply: affect sticks around. As [Thiel \(2015, p. 40\)](#) states, the stickiness of affect is “what gets named, remembered, embodied, and performed, serving as a catalyst in the ways we learn to become and move through the world.” For some students affect will increase their capacities for literacy learning; and for others, it will diminish it. Seen in this way, attending to affect in educational contexts is a matter of critical importance.

Recognizing affect and textual variations

In this section, I revisit encounters with three students previously introduced in other publications (I cite the publications below for those interested in a more fulsome background on these young people and their classroom and community contexts.) Affect played a key role in each of these revisited encounters in Canadian classrooms. Crystal, Ally, and Sara, in different ways, were students who appeared to be out of step, to varying degrees, with what was expected of them in the particular encounters with literacy I relate below. However, when their participation in their classroom assemblages is examined with post-colonial and post-structural concepts of affect in mind, alternative understandings of the three girls and their literacy learning become possible.

Pikachu bonding

I first return to the story that opens this article. While we rarely discussed Crystal’s ways of being in the classroom or her textual productions, her teachers did note that they interpreted things such as the Pikachu calling as maladaptive, attention-seeking behaviors that were best left unacknowledged. However, through thinking with affect, an alternative understanding becomes possible.

Crystal, a 10-year old girl, of Métis heritage, was a participant in a 2-week long series of half-day workshops with a local comedian, Ben Canon ([Lenters and Whitford, 2018](#)). In the comedy literacy workshops, as the students called them, Ben worked with Crystal’s class of 5th-grade students to immerse them in processes of composing comedy. Early on in those two weeks, Crystal, who at times struggled in her relationships with classmates and teachers, learned that Ben was fond of Pikachu. Pikachu also happened to be her favorite Pokémon character. From that time forward, she frequently sought out Pikachu conversation with Ben, sometimes interrupting discussions he was having with other students. She began bringing her stuffed Pikachu to every workshop and soon started wearing a Pikachu costume to school. Crystal clearly formed a bond with Ben, sparked by the electrifying character of Pikachu.

At some point, mid-way through the two-week workshop, Crystal began seating herself during whole-class discussions beside the whiteboard that sat on its easel to the left of the teacher’s chair. The whiteboard was primarily covered by a large pad of paper but Crystal found a small open corner and would quietly illustrate the many class stories that were collaboratively composed during the workshop. At times she selected the character of Pikachu for these illustrations and other times the figures more closely resembled those taking shape in the large group’s emerging collaborative story productions.

Not wanting to reinforce what they identified as inappropriate classroom behavior, Crystal’s textual productions—the Pikachu calling, interruptions to conversations, the stuffed Pikachu and costume, and the white-board illustrations—were not attended to by her teachers. In this way, it seemed to me that they were considered “surplus” ([Leander and Ehret, 2019](#)) (albeit, unconsciously) to the everyday business of working together well as a class. Crystal struggled with the other aspects of the workshop and I found myself wondering if the affective assimilation ([Dernikos, 2020](#)) that rendered her productions surplus might have contributed to these struggles. Crystal’s affective bonds to Pikachu and Ben, and the texts, verbal and visual, that affect produced might instead have been recognized, welcomed into the literacy circle, and could have provided openings for Crystal’s textual productions to extend into other modalities, such as writing.

Book club instigations

Ten-year old Ally had a complicated relationship to reading. She professed a love for reading when it involved certain kinds of texts, for example, graphic novels; and to roundly dislike it, in relation to the reading of other types of novels ([Lenters, 2014](#)). This meant that in school, she loved free reading time; however, participation in her classroom literature circle assemblage was fraught. In part,

this was connected to her school library's novel sets—Ally's affective disorientation to the somewhat limited offerings put her off—and the normative constraints of scripted roles in student-led literature circles. But it also had to do with who was in her literature circle group. A rivalry between Ally and Deanne, years in the making, formed a relational undercurrent of affect in Ally's experience of her lit circle group. Deanne appeared to be unaware of it, but the rivalry was felt deeply by Ally, who carried a sense of being overshadowed by Deanne's accomplishments. These aspects of her participation in literature circles created an intensity around student-led, collective reading experiences that marginalized Ally in the classroom literacy club (Smith, 1988) and led to what her teachers (and report cards) characterized as poor performance in reading.

When the opportunity to form the English Roses book club emerged in her housing co-op's shared outdoor space, things changed quite dramatically, albeit momentarily, for Ally (Lenters, 2018). The arrival of her long-awaited copy of Madonna's *English Roses: Friends for Life* (Madonna, 2007), her friends' exuberant interest in the book, the formation of the English Roses book club, and the embodied ways in which they collectively engaged with the book offered an attractive alternative to the aspects of literature clubs that Ally found so disorienting. With just one copy of the English Roses, Alli and four friends found the enthusiastic engagement with literature that her classroom literature circles (modeled on Daniels, 2002) had been unable to generate. In contrast to the disillusionment she experienced in the classroom lit circle, the book club brought meaningful discussions, electrifying embodied (re)readings, and a joyful sense of belonging, as allied Madonna lovers gathered. This palpable affect carried over into the classroom for several days, as I witnessed Ally return from recess and lunch breaks, book in hand and book club members in tow, with her head held high. This transformation stood in stark contrast to her downcast demeanor days and weeks prior, comportment that seemed to return when the English Roses book club came apart.

In the time I knew Ally (the whole of her 5th-grade year), the normative practices and the teacher-assigned group members that configured the literature circles in Ally's classroom had become highly constraining for her. In contrast, the spontaneous formation of her out-of-school book club, while precarious, were transformative and defied the constraints that threatened her literate development. Affect (re)configured Ally and her relationship to collective reading experiences. Simultaneously, even as Ally was transformed, so too was the assemblage we recognize as book club. The transformed, affectively shaped book club became a place of shared reading and embodied response. It fostered intensities that extended beyond the club meetings, affecting not only relationships to reading and texts but also interpersonal relations. As they came into a relationship with each other, the affect sparked between Alli and her book club had a mutually reconstituting effect on both assemblages. What might have happened had this intensity and the (re)configurations been noticed in Ally's classroom? Could the literature circle, as a textual production in and of itself, have thereby been transformed for all of the members of Ally's classroom assemblage?

When words are not enough

Eleven-year old Sara considered herself shy—reluctant to speak out in her 6th-grade class. As a child of South Asian descent, Sara was by no means in the minority in her culturally and linguistically diverse class (see Lenters and Whitford, *in press*). Yet, in the scene I describe next, Sara's experiences in a particular classroom improv scene animate the workings of a racializing assemblage (Weheliye, 2014) and the fleshy, affective responses to it that served to disrupt its normativizing flow. Her teacher's experiment with classroom improv had started in September with the idea that other topics would be pursued after a couple of months. However, the 30 members of the class, some of whom were familiar with improv and some not, quickly came to adore the 2 hours per week spent doing improv. Sara, like many in the class, professed to having an initial preference for being an audience member and leaving the improv performance to others. However, after a few weeks of observation she found herself compelled to take the stage.

In Sara's class, improv operated around two central rules: "Yes, and" and always make your partner look good (see Fey, 2011), rules that the class interpreted as, "No denial" and "No shining." In other words, the 6th-grade players were to endeavor to take up and build on offers (ideas, directions, suggestions, etc.) made by other players, as much as possible, and to work collaboratively to make each other look good by not personally dominating the scene. These rules and the supportive milieu they fostered most of the time, along with the teacher's gentle encouragement, soon drew even the most reluctant to Sara's classroom stage.

The classroom rules for improv were meant to guide the interactions between players on the stage, that is their embodied textual productions. However, in one particular scene, which we titled, Making Macaroni, it was affect that guided the textual production. Sara, Colton, and Liam were to improvise a scene in which they were trapped inside a computer. From the start, and throughout the scene, the boys (Colton, of Anglo-Saxon heritage, and Liam, of Asian heritage) excluded Sara (of South Asian heritage) by only speaking with each other. Sara's rather clever attempt to break into the scene by becoming Siri, the Apple IOS virtual assistant, was at first ignored by the boys. When the teacher intervened, Sara repeated her offer: "[using Siri's voice] How may I assist you?" and Colton responded with, "I'm going to disable you, Siri. You're so annoying!" Colton's retort brought uproarious laughter from the audience. As Colton continued with his "shining," Sara disrupted the scene with her own shining, moving between the boys to get to the side of the stage, saying, "I'm going to make macaroni." Seemingly unfazed, the boys continued their excluding dialogue until Sara returned, bearing a large, imaginary bowl of macaroni and dumped it in Colton's face with a peremptory, "Here, have some macaroni and cheese!", this time inviting a collective gasp, followed by silence from the audience. This type of exchange was repeated a few times during the rest of the scene.

The affects generated in this scene were multiple: exclusion, courage, frustration, laughter, shock, and perhaps embarrassment. I argue that these affects then fostered various types of textual (verbal and embodied) productions—for example, Sara-Siri cutting off the boys' excluding dialogue with movement and the introduction of offers not connected to their attempted repartee. Following

the initial Siri gambit, Sara-Siri's textual productions, as they matched the boys' exclusionary productions, technically broke with the classroom rules of improv, over and over again.

The boys' break from the improv rules drew laughter from the audience; Sara-Siri's, dismay. The scene serves as an illustration of the way affect can be used by some for normative, reinforcement of racializing assemblages in which some bodies (Sara and Sara-Siri) were excluded by a gendered and racialized status quo perpetuated by those accustomed to holding the stage (Colton and Liam). It also demonstrates how affect may be used to turn the tables on textual production. Exclusion may have been the affect generated by the boys to work against Sara; however, Sara, instead, used it to empower the character of Sara-Siri.

With her unorthodox movements, Sara-Siri established a place for herself in the improv scene (Blackburn, 2016). Her moves disrupting the excluding assemblage perpetuated by the boys. The "fleshy humanness" of her actions—the textual production sparked by affect that disrupted the male dominated narrative Colton and Liam were perpetuating—allowed Sara-Siri, paraphrasing Burton, to thrive and survive in unorthodox ways (Burton, 2017, p. 35), in both the improv scene and the larger classroom assemblage. The teacher in Sara's classroom noted the racializing assemblage the boys were creating in the storied world of the Making Macaroni improv scene. His initial intervention and invocation of the classroom rules of improv helped Sara gain entry to the assemblage, an entry she then ran with through spoken and embodied textual productions. As Sara herself broke with classroom rules of improv, he did not intervene, allowing her fleshy responses to the boys. Through these supportive moves, Sara-Siri's clever and unorthodox ways with spoken and embodied texts were both validated and allowed to do their work in disrupting the boys' attempt to dismiss and exclude.

Openings

Affect should matter greatly to educators. As Stewart (2010) reminds us, affects, as "pre-personal intensities lodge in bodies. Events, relations and impacts accumulate as the capacities to affect and be affected" (Stewart, 2010, p. 339). Put simply: affect sticks around.

I offer these encounters with Crystal, Ally, and Sara to, following Leander and Ehret (2019), "generate an alter-economy of literacy research and pedagogy wherein new modes of expression and encounter value the excess of experience by allowing that excess to become what could be" (p. 23). This alter-economy of the girls' forays provide important questions to consider. Most notably: What might happen to young peoples' engagement with classroom literacies were educators to recognize the kinds of orienting and disorienting, transformative and normalizing affects that arise in classroom assemblages?

Affect cannot be readily measured. And for this reason, it may be eschewed in schooled literacy learning contexts. However, tuning in to affect can support critical, relational pedagogies (Dutro, 2019). Attending to the various faces of affects, and the bodies in which they bloom, provides important avenues for understanding and supporting young people's textual productions. Such attention can alert educators to racializing assemblages and the normative practices that so easily, and all too commonly, marginalize certain students. Finally, attuning to young people's affective responses (the reluctances and the delights) and watching for the unsanctioned textual productions (the side-conversations, notes passed, doodles drawn, movements made), can provide educators with clues and directions for encouraging all students to feel they are recognized members of the classroom assemblage we think of as the literacy club.

Overview

In this article, we explore several aspects of positioning and positionality in relation to posthumanism. In particular, we consider an increasingly common framework in literacy studies, that of Positioning Theory, which originated in the work of Davies and Harré (1990) and Harré and colleagues (e.g., Harré and Van Langenhove, 1991, 1999a; Harré and Moghaddam, 2003). We ask: what might Positioning Theory gain from posthuman perspectives? This question is in response to Gergen's (2015) call for theorists to move from "issues of philosophic grounding to social utility" (p. 290). That is, we aim to consider not only philosophical issues around positionality and posthumanism, but also how theories of positionality can be potentially be used for transformation and change, rather than merely to represent phenomena. With those intentions in mind, we attempt to consider theory as a utilitarian tool for literacy scholars and those interested in literacy. We define literacy broadly with emphasis on discourses that shape and define literacy processes. This includes literate processes related to traditional alphabetic systems (e.g., reading a book on paper) or processes pertaining to digital literacies (e.g., composing a multimodal text). This conception of literacy is situated within social, discursive, and multimodal perspectives. Since much has been written about these areas (e.g., Cope and Kalantzis, 2000; Gee, 2015; Jewitt and Kress, 2003; Unrau et al., 2019), we do not review these perspectives here.

To begin our exploration, we briefly define posthumanism. Next, while making some comparisons with Positioning Theory and Davies and Harré, we consider the writings of two scholars, Foucault and Hollway, who have influenced scholarship in posthumanism and positioning. Third, we provide a brief overview of Positioning Theory, primarily as explored in the work of Rom Harré and other positioning scholars. We conclude by discussing three key intersections of posthumanism and positioning: critical positioning and literacy, embodiment, and affect, and review areas of synergy with positioning.

Perspectives on positioning and posthumanism

Posthumanism is generally viewed as a reaction to, or questioning of, the aspects of Enlightenment technical, rational, objective thought and beliefs that placed humans at the center of life that gave rise to humanist philosophies. Wolfe (2010) notes that Foucault takes issue with such assertions, opting instead to consider these as tensions, and others (e.g., Taylor and Hughes, 2016) observe such a direct lineage is not entirely accurate. However, as a starting place, it can be helpful to make this comparison while noting that posthumanism does not require the rejection of all that has come before. Posthumanism is about decentering human (or anthropocentric) perspectives that neglect the role of objects, animals, technologies, materials, and biologies. The term "posthumanism" itself is somewhat misleading. Wolfe (2010) articulates that posthumanism is not a renunciation of

the human, but rather that it “actually enables us to describe the human and its characteristic modes of communication, interaction, meaning, social significations, and affective investments with *greater* specificity” (p. xxv, emphasis original). As a theoretical lens, posthumanism is additionally challenging since it spans embodiment, affect, technology, and artificial intelligence among other areas.

Vermeulen (2014) defines posthumanism as a shift “to a more affirmative engagement with the world outside the text—with bodies, animals, affects, technologies, and materialities of different kinds” (pp. 121–122). Precisely because literacy scholars do not have theories that adequately address this shift, Leander and Burris (2020) assert that posthumanist theory can be useful. In *Posthumanism in Literacy Education: Knowing/Becoming/Doing*, Kuby et al. (2019) demonstrate what it means to take up posthumanist theory and apply it to literacy. Zapata et al. (2018) articulate that posthumanism and other critical theories “seek to reimagine and reconsider understandings about the ways multifarious entities enter into, sustain, and enmesh with worldly relations” (p. 481). Positioning Theory precisely focuses on the interactional relations that are intrinsically social, networked, and embodied. Fundamentally, positioning emphasizes the nuances of relationships—relationships with group identities, with other people, and with oneself. These relations are socially-distributed and not bound by time.

Applying posthumanist ideologies to literacy education, Zapata et al. (2018), express the value of considering the feminist perspective of how each of us is able to respond, regardless of whether we desire to be included in particular relational entanglements. Parrott (2003) echoes this sentiment, asserting that the dynamism of Positioning Theory lies in how it implicates people within any interaction as active participants (p. 33). This is critical in that Positioning Theory’s idealistic function is to enlighten those working in education and other fields of the complexity of human entanglements, and how human interrelations can elicit unconscious human biases. Positioning Theory has the potential to encourage self-reflection of how we position ourselves, how we are positioned, and how we position others—whether others are people, things, or animals. As a critical theory, posthumanism can help Positioning Theory focus not only on language as discursive but also on all aspects of positions whether related to people, animals, technologies, machines as well as other humans.

Foucault

In much of the scholarship on positioning and positionality, Foucault and Smith (1969/1972) is cited as the origin for subject positions (e.g., Deppermann, 2013, 2015). While Tirado and Gálvez (2007) discuss contributions of Foucault’s work to Positioning Theory, writing about their own line of thought, Harré and collaborators point to Hollway (1984/2005) as influential. In her writing, Hollway refers to Foucault’s foundational notion of subject positions. She recognizes a gap in Foucault’s account of positioning and discourse as she writes about heterosexual gender differences and the production of subjectivity: “He [Foucault] still does not account for how people are constituted as a result of certain truths being current rather than others how is it that people take up positions in one discourse rather than another?” (p. 234). These questions, Hollway observes, demand critical examination of hierarchies and social histories so as to illuminate patterns of positioning within discourses. This “also requires a question concerning the *investment* in that position” (Hollway, 2005, p. 234, emphasis original). She acknowledges that Foucault’s usage of the term discourse and its historical nuances are crucial in understanding positions (p. 226). Discourse positions individuals within external systems because discourses are produced by power within a social order. For example, education allows access to discourse but simultaneously controls the appropriation of discourses and access to power of those discourses.

Hollway

In her writing, Hollway (1984/2005) writes of taking up positions and positioning oneself with regard to gender:

Discourses make available positions for subjects to take up. These positions are in relation to other people. Like the subject and object of a sentence ... women and men are placed in relation to each other through the meanings which a particular discourse makes available ... (2005, p. 233).

Positions are not predetermined and do not exist independently but are produced and “re-produced,” as Hollway affirms, through interaction. Hollway’s intentional use of the hyphen signals the ways in which any day-to-day practice is individually a production. These re-productions produce (and reproduce) gendered subjectivity. Hollway focuses on positioning in discourses and how different discourses “make available different positions and different powers” (2005, pp. 226–227). She emphasizes Foucault’s historical perspective on discourses and the importance of individual histories. Davies (1991) echoes this perspective in her feminist writings on positioning stating that “discourses, embodiment, and the material force of the discourses through both individuals and social structures” (p. 43) are related to subject positions and agency. Positions available to be taken up exist not only in conversational discourses but in “body/landscape relations” (Davies, 2003, p. 279). That is, discourses are embodied and shape the power and agency that individuals can access.

Harré's Positioning Theory: a brief summary

In *The Self and Others* (2003, p. 139), Moghaddam, Hanley, and Harré remark that Positioning Theory is derived from feminist developmental and social psychologists [Hollway \(1984\)](#) and [Davies \(1991\)](#). In their original article introducing Positioning Theory, [Davies and Harré \(1990\)](#) write:

Once having taken up a particular position as one's own, a person inevitably sees the world from the vantage point of that position and in terms of the particular images, metaphors, story lines and concepts which are made relevant within the particular discursive practice in which they are positioned (p. 46).

This widely quoted passage is a succinct expression of the metaphor of positioning. While the metaphor is essential, Positioning Theory is about more than merely a metaphorical sense of where one is located within an interaction. [Davies and Harré \(1990\)](#) seek alternatives to the static "concept of role in developing a social psychology of selfhood" (p. 43) and observe that positions:

permit us to think of ourselves as a choosing subject, locating ourselves in conversations according to those narrative forms with which we are familiar and bringing to those narratives our own subjective lived histories (p. 52).

Even in interactive approaches, such as Goffman's frames or footing, roles are viewed as static or fixed (see [Davies and Harré, 1990](#), pp. 52–55; [Harré and Slocum, 2003](#), pp. 126–127). By contrast, positions are dynamic, fluid, and immanent, representing "a cluster of rights and duties to perform certain actions" ([Harré and Moghaddam, 2003](#), p. 5). People understand and experience positions through lived narrative experience. This includes beliefs, emotions, and subjective histories in addition to knowledge of social structures and their accompanying rights and duties. This is not to say that "choosing subjects" are fully independent. [Parrott \(2003\)](#) indicates that positioning is "dynamic ... extending the range, flexibility, and creativity of self-definitions that are under negotiation" (pp. 32–33). However, positions are always linked to "cultural, legal, institutional, conversational and personal moral orders" ([Van Langenhove, 2017](#), pp. 5–6) which influence a person's agency or perception of agency.

Storylines and the positioning triangle

[Davies and Harré \(1990\)](#) describe the "metaphor of an unfolding narrative" (p. 53) where discourses constitute one or more positions within a storyline or storylines.

If we are to come close to understanding how it is that people actually interact in everyday life we need the metaphor of an unfolding narrative, in which we are constituted in one position or another within the course of one story, or even come to stand in multiple or contradictory positions, or to negotiate a new position by "refusing" the position that the opening rounds of a conversation have made available to us.

[Davies and Harré \(1990, p. 53\).](#)

There is a strong relationship between positioning, narrative, and conversation as ongoing, enacted processes. Storylines emphasize the "dynamics of social episodes" and how various individuals may contribute as storylines unfold ([Harré and Moghaddam, 2003](#), p. 6). The Positioning Theory triangle or triad has emerged as a key representation and analytic tool in Positioning Theory. Early theoretical works were limited in specifics of how to conduct analysis, but theorists proposed that analysis could begin from any of the triangle's vertices: storyline, position, or speech acts ([Harré and Moghaddam, 2003](#), p. 9), also sometimes referred to as "Speech and other acts" (e.g., [McVee, 2011](#), p. 6). Examples of analysis using the positioning triangle to analyze different scales of social encounters can be found in [Harré et al. \(2009\)](#). The triangle has also been adapted as a Positioning Theory Diamond to support more refined and systematic analysis and account for identity ([Slocum-Bradley, 2009](#)).

Whether conceived of as a triangle or diamond, as an analytic tool the representation can be applied to conversations. Conversations may be face-to-face dialog, but [Van Langenhove \(2019\)](#) cautions that the term "conversation" must be understood also to include other encounters such as when a person reads a sign prohibiting smoking. The essence of the social world is such "the primary social reality that can be conceived as a species-wide and history-long network of people speaking to each other in an environment that is socially meaningful" (p. 64). In prior work, [Harré and Van Langenhove \(1999b\)](#) elaborate that Positioning Theory takes as its starting point:

the idea that the constant flow of everyday life in which we all take part, is fragmented through discourse into distinct episodes that constitute the basic elements of both our biographies and the social world. The skills that people have to talk are not only based on capacities to produce words and sentences but equally on capacities to follow rules that shape the episodes of social life. Not only what we do but also what we can do is restricted by rights, duties and obligations we acquire, assume or which are imposed upon us in the concrete social contexts of everyday life (p. 4).

McVee et al. (2019b) have also refined the positioning diamond (Slocum-Bradley, 2009) to represent moral fields and the ways that storylines, speech and other acts, and positions are not bounded by linear representations of time. "The distinction between past, present, and future does not go over neatly into psychological time, partly because the social and psychological past is not fixed. The social future can influence the social past" (Van Langenhove and Harré, 1999, p. 15). Researchers have demonstrated how embodied interactions can be analyzed not only for actual spoken or written conversation but also for multimodal meaning making within moral fields and to consider identity, rights, and duties (McVee and Carse, 2016; McVee et al., 2019a) within research tied to embodiment and material artifacts (see McVee et al., 2021).

Posthumanism and critical positioning: examples from literacy research

Over the past few decades critical theories have increasingly been applied to literacy research (Anders et al., 2016; Brooks, 2019; Luke, 2019; Vasquez, 2014; Willis et al., 2008). We do not provide a review of this work, but assert that it provides a useful entry point for exploring intersections and potentials of posthumanism and Positioning Theory. Zapata et al. (2018) posit that posthumanism helps bring recognition to the ways that "seemingly disparate critical approaches (feminism, anticolonial and antiracist thought, technology studies, ecology, etc.) have a common ground in directly challenging the ways humanism has restricted politics and education" (p. 480). The definition draws attention to the importance of understanding the critical stance in the dominant discourse and academic discourse. Restrictive policies are usually designed by individuals who have power, authority, and agency (Davies, 1991) in dominant discourses. Individuals who are from different/nondominant linguistic, racial, and cultural backgrounds are usually positioned as marginalized groups who have duties and rights to perform social acts without agency in the discourses. Not only are these unequal positions historically and socially situated in the broader discourses, but these positions in relation to race or other critical issues are also consciously or subconsciously embedded within everyday teaching and learning in the classroom discourse. Zapata et al. (2018) call for a focus on "real social and physical materialities of race and class on a human" (p. 491). Several examples can illustrate this.

In 2010, the Tucson Unified School District banned the Mexican-American ethnic studies program (Delgado, 2012). This enactment dematerialized (Zapata et al., 2018) Latinx students' bodies in relation to race and ethnicity and was precipitated by those who had power and authority through a variety of discourses. Latinx students were positioned as others who had some rights (e.g., the right to go to school) but not the agency in schools to decide curriculum (i.e., Latinx students were no longer able to decide to engage with their own cultural materials). Similar events also occur in other institutional discourses. For instance, in 2019, the African American Studies program at the University of Buffalo was defunded because the number of African American faculty had decreased (The Spectrum, 2019), and the African American Studies program was merged into another department. Students were not given choices to decide if they wanted to maintain the program or to hire new faculty. These cases demonstrate positions and power related to institutional discourses. From the posthumanist perspective, however, research related to education and power structures should not just focus on dualisms (Davies, 1991) such as ethnic studies or no ethnic studies. Rather, expanding humanist perspectives by deconstructing dualisms may provide access to examine positionality within institutional discourses. Amplified attention on how various positions come into play in the institutional discourses would illuminate the influence of social hierarchies on interpersonal dynamics. Positioning Theory helps examine nuances (i.e., intersectional positions) concerning materials of critical issues such as "racism, classism, and sexism" (Zapata et al., 2018, p. 491) in the institutional discourse. Even in these cases, further analyses could analyze material or ideological positions pertaining to culture, law, conversation, and personal moral orders (Van Langenhove, 2017) surrounding institutional decisions. Such critical examination and reflection may illuminate unconscious (and perhaps unintentional) biases in decision-making that produce privilege/oppression and access/deprivation.

Not only do the posthumanist perspective and Positioning Theory help people examine power structures in societal and institutional discourses, but they also help educators and researchers examine unequal power positions and critical issues in the literacy field. Zapata et al. (2018) utilize the perspective of materiality to emphasize the materials of critical issues and ways that racism, sexism, or classism are entangled with literacy practices in the classroom. The bodies of students from linguistically and racially diverse backgrounds are often dematerialized. That is, bodies are often treated as if they are cut off from the event, are unimportant, or are inconsequential (Zapata et al., 2018). For example, as the unequal positions are sustained in school discourses, teachers experience challenges when working with the students. In the United States, 79% of public school teachers are White monolingual teachers (U.S. Department of Education, 2016). How can the teachers be prepared for working with their students? One way to achieve this purpose is to examine individual "subjectivity" (Davies, 1991, p. 47) and "become more multiple, flexible and inclusive of different points of view" (p. 51).

A number of scholars have utilized Positioning Theory to examine White teachers' subjectivities and self-critique in multiple ways, such as book-club discussions and cross-cultural experiences (Brock et al., 2006; Brock and Pennington, 2014; Glazier, 2005; McVee et al., 2004; McVee, 2014). The discussions on critical issues enabled the teachers to examine their own subjectivities in relation to the dominant discourse, learn about their students' positions from new perspectives, shape their beliefs as literacy educators, and reconsider their instruction and pedagogy for supporting all students. For example, drawing upon Positioning Theory, Brock et al. (2006) explored how six in-service teachers who enrolled in a cross-cultural summer course re-examined their own perspectives on culture and literacy instruction for students who are from diverse backgrounds. Participants had opportunities to engage in online discussions on multicultural texts and then traveled to Costa Rica to acquire cross-cultural experiences by staying with local families. The authors found that teachers had experiences with displacement when they entered a different culture and

they repositioned themselves in new storylines that were different than those they understood through their “own interpretive lenses” (p. 58). In this case, educators used Positioning Theory to re-examine their position and beliefs. Similarly, [McVee et al. \(2004\)](#) investigated White female teachers’ learning and positioning in relation to race and class when participating in book club discussions. Not only did the authors draw upon Positioning Theory as a tool, but they also developed new kinds of positioning as analytical lenses to gain insights into how the participants examined their positions and challenged their thinking in relation to critical issues and literacy. Positioning Theory has expanded peoples’ relationships and lived worlds through illuminating problematic, previously unconscious biases. Using self-reflection to crystallize positionalities creates more flexible social interactions, which has the potential to alter the influence of power in social hierarchies.

These studies demonstrate aspects of critical literacy and position concerning race, class, and gender in teacher education. Indeed, power dynamics are embedded in all discourses. Instead of viewing colorblindness as an approach to teach all children, it is significant that teachers examine their individual positions in relation to the discourses, recognize “the materialities of race,” “open up different possibilities” ([Zapata et al., 2018](#), p. 490), and explore “what it meant to be an effective and responsible teacher for all children” ([McVee et al., 2004](#), p. 13). Posthumanism and Positioning Theory can be effective theoretical lenses to identify power dynamics and to assist teachers, and others, in identifying the ways that discourses shape pedagogical decisions and actions but also in helping transcend racial, cultural binaries that are counter to democratic possibilities ([Snaza et al., 2014](#)).

Positioning and embodiment

Literacy studies that adopt posthumanism or Positioning Theory as an analytic or explanatory framework most often also draw from critical theories. Despite this critical focus, many literacy studies do not explicitly develop or explore embodiment or affect. Writing of posthumanism in the context of literacy studies, [Zapata et al. \(2018\)](#) articulate that the “philosophical perspectives on knowing (epistemology), be(com)ing (ontology), and doing (axiology)” are the basis of posthumanist scholarship (p. 478). Positioning Theory shares some of these same roots through embodiment. Although not always foregrounded, Harré’s body of work (cf. *Personal Being*, 1983) makes clear that embodiment is a fundamental tenet of Positioning Theory. We propose that the “mind extends beyond the skin” ([Wertsch, 1991](#), p. 14), in that mind is discursively produced (e.g., [Harre and Gillett, 1994](#); [Harre and Stearns, 1995](#)) and socially distributed ([Gee, 1992, 1997](#); [Lave and Wenger, 1991](#); [Rogoff and Lave, 1984](#)). The *New London Group* (1996) similarly assert that “the human mind is embodied, situated, and social” (*New London Group, 1996*, p. 82; emphasis added).

[Roelvink and Zolkos \(2015\)](#) connect *affect* with *embodiment*: “affect is often interpreted as a recognition and validation of embodied and emotive forms of knowledge production” (p. 4). They understand the importance of the body in terms of identity and intellectual awareness. The body is defined through the multiple and varied identities it creates, as well as through bodily movement. In this regard the body does not “remain fixed or static but [is] mediated by processes and practices that produce dynamic points of intersection and connection” ([Blackman, 2009](#), p. 107). The potentiality of embodiment can be observed in different forms, including embodied knowledge (i.e., spatial embodiment, and embodied practices). Thus, the role of embodiment can be understood in various ways:

1. Embodied knowledge
2. Embodied practices
3. Embodied discourses

Embodied knowledge

Embodied knowledge, or what [Bourdieu \(1986\)](#) labeled as “embodied capital,” emphasizes the value of identity-based knowledge. [Fairbanks and Ariail \(2006\)](#) explicate this idea, arguing this is knowledge that is embodied in thoughts or perceptions through which individuals engage and interact with the material world. They emphasize that embodying positional identities gives an opportunity for individuals to “resist and revise them,” (p. 316) creating new opportunities and ways to exist in the world. Embodied capital is demonstrated through a series of power relations, including race, class, ethnicity, nationality, gender and so on. Each of these facets of identity is connected with capital—some more highly valued than others—in our social world. For example, as explored in Bourdieu’s scholarship racial hierarchies have presumed that some forms of racial capital are more or less valuable than others. Historically in the US, for example, the capital of White people has been of greater perceived value than that of other races, thus giving Whites more access to discourses of power.

Embodied practices

“Embodied practices” ([Veninga, 2009](#), p. 116) are “the ways in which individuals do or perform who they are” ([Tzou and Bell, 2012](#), p. 267). This has been exemplified in literacy scholarship. In examining students doing digital video production, [Rogers et al. \(2010\)](#) observe that students embody genre practices in how “they borrow, juxtapose, hybridize, or transform genres and modes” through video composition practices to generate “new discourse narratives” (p. 301) that function both as locations of subject positions and as methods of social critique. With regard to counterstories, [Winslade \(2012\)](#) notes a similar concept arguing that this literary genre “embodies in narrative practice the impulse toward resistance in an intentional construction of an identity story. It stresses the value

of agency" (p. 29). These studies represent aspects of literacy as an embodied practice; as [McVee et al. \(2005\)](#) argue: "Language is a way of *doing* things in the world" (p. 546, emphasis added).

Embodied discourses

This leads us to the third role of embodiment, closely related to embodied practices: embodied discourse. [McVee et al. \(2005\)](#) describe how embodiment is rooted within our sociocultural worlds through language:

The discourse processes required in the moment are embedded in cultural histories not just of individuals but of kinship groups, social classes, and political ideologies. It is not merely words but social and cultural practices, opportunities, and interactions that must be provided. In addition, these experiences, opportunities, and interactions must allow for a child to engage with a range of mediational artifacts, both material and ideal, thus tying language to authentic material and cognitive practices and embodied activity (p. 546).

Embodied discourses, especially those that are multiple and contradictory ([Fitch, 2003](#)), are an active process. An example of this can be seen in an engineering literacies club ([McVee et al., 2017, 2019a](#)) wherein teachers taught third-grade students about engineering skills and disciplinary literacies and worked to instill Engineering Habits of Mind ([Royal Academy of Engineering, 2014; McVee et al., under review](#)). Teachers used engineering discourses which were, over time, adapted by the students. These discourses were more than the cultivation of scientific terminology—they represented new ways of thinking, perceiving, working collaboratively, asking questions, and using creative problem-solving skills to accomplish a shared goal involving material artifacts ([Silvestri et al., 2021](#)). The phrase *Engineering Habits of Mind* captures the interactions that took place in this engineering literacies club: using engineering discourses began as the adoption of jargon and evolved into the development of an engineering mindset through the use of artifacts and embodied interactions (e.g., physical and social positionings with, around, and through artifacts). This embodiment of discourse transformed research participants from novice students to "expert" third-grade engineers.

Embodied being

Embodiment implies a physical being that lives in a social world. Posthumanism can offer unique insights to Positioning Theory, and the field of education, in this sense. [Zapata et al. \(2018\)](#) write: "posthumanist scholarship is rooted in a relational ontology, meaning that we come to know through our being with and in the world" (p. 479). As articulated by [Gee \(2000\)](#), the field of education has been notorious for dismissing the physical bodies of students, metaphorically having students check their bodies at the door. Only in recent decades have academics begun to make the shift to perceive students in their entirety. [McVee et al. \(2005\)](#) propose this to be "a paradigm shift that involves radically transforming our perspective so that we are considering 'minds-on-bodies-on' as students engage the body-mind and researchers consider what it means to learn from a body-mind perspective" (p. 157). Zapata et al. also acknowledge the way that bodies have been dismissed—or outright ignored—specifically in terms of class, race, and gender. Positioning Theory is an attempt to subvert this idea of students leaving their bodies at the door by focusing specifically on how identities, privileges, and power are constructed, reproduced, and sustained, but also how they may be dismantled, transformed, adapted, or challenged. Posthumanism and Positioning Theory can readily be used in conjunction with each other to illuminate complex relationships across all manner of educational domains and relations.

Finally, we must note that not all embodiment happens within the body; rather, spatial embodiment is the perception of geographical spaces as embodying histories, ideologies, and value-systems ([Green and Whitsed, 2012; Hungerford-Kresser and Vetter, 2012](#)). [Tzou and Bell \(2012\)](#) agree that places embody "narratives and norms," and social interactions within a learning environment are not "neutral or random" but are entrenched in "historical and spatial contexts that invite or prohibit opportunities for learning" (p. 266) and engagement.

Positioning and affect

In "Posthuman Affect," Pieter Vermeulen addresses the connection between embodiment and affect: "a posthumanism that insists on embodiment cannot simply be reduced to one particular emotive disposition; instead, it generates a field of affective possibilities that different posthumanist practices can inhabit in different ways" ([Vermeulen, 2014](#), p. 124). One of these "affective possibilities" is the complex, nuanced role identity plays in human relationships. Posthumanism, not unlike Positioning Theory, considers affect integral to the "interplay of bodies" ([Roelvink and Zolkos, 2015](#), p. 2). Considering the fundamental aspect of humanity to be relational, posthumanism emphasizes the importance of human connections—the animation between people. Roelvink and Zolkos, in their piece "Posthumanist Perspectives on Affect," emphasize that recent scholarship on affect "has used the category of 'the animate' ... as synonymous with a certain *force of aliveness* and of a *potential for becoming*" (2015, p. 2, emphasis original). They define the primary facets of affect to be sensation, subjectivity, sociality, and politics (p. 4). Positioning Theory considers similar tenets that affect how people position each other—especially through social subjectivity, relationships, and identity. In his work [Harré](#) argues that emotions and meaning are grounded in the bodies as material things and social beings ([Harré, 1983, 1991](#)). Positioning Theory

functions on multiplicity—the position of one person, without anything in relation for comparison, is meaningless; positioning depends on interrelations.

Positioning of self and others

How people position others and are positioned by others is impacted by gender, social class, race, ethnicity, linguistic background, and other relational power dynamics. Referencing positioning scholars [Harré and Van Langenhove \(1999a\)](#), [Arkoudis \(2005\)](#) articulates that “people bring to their conversations different rights and responsibilities that reflect differences in power relations and affect their ability to position themselves and each other” (2005, p. 175). These social identities are related to how students position themselves (defined as “intentional self-positioning”), and how they position others (defined as “interactive positioning”) that impacts student learning ([De Costa, 2011](#), p. 349). We detail examples of these complex interactive possibilities below.

The following studies examined the roles of class and gender in regards to Positioning Theory. In a study focusing on student-led discussions in a classroom, [Clarke \(2006\)](#) found that gender and class affect student dialog and “discursive interactions” (p. 55). Social class, through this lens, was also examined by [Payne-Bourcy and Chandler-Olcott \(2003\)](#), who found that social class affected a research participant’s literacy learning due to differences in community language practices and academic language practices. Similarly, [Freeman \(2010\)](#), found the needs of students from working class families were handled by teachers/staff differently. She also found that working-class parents’ backgrounds influenced how they participated and also whether they did participate. It is essential to note that social class influenced perceptions and emotions tied to participation (or lack of participation), but social class alone does not determine positions. Importantly, Freeman discovered that parents were not always passive in these social interactions. In their affective and agentive responses, parents also demonstrated what they believed to be “effective countermeasures in their efforts to reposition themselves and their children in the eyes of the administrators” (2010, p. 189).

Race is also a critical factor that impacts peoples’ positioning (e.g., [Glazier, 2003](#); [Harré and Slocum, 2003](#); [Mahar, 2001](#); [McVee, 2011](#); [McVee et al., 2004](#); [Monrouxe, 2010](#); [Rickford et al., 2004](#); [Vetter, 2013](#)). [Monrouxe \(2010\)](#) examined how medical students’ perceptions of their patients were linked to race, articulating that race “affects doctors’ feelings of affiliation toward patients” (p. 44) paired with their belief regarding how likely they thought patients were to follow to the doctor’s recommendations. Positioning and race is similarly disconcerting within an academic context. [Rickford et al. \(2004\)](#) discussed historical injustice and oppression that has plagued academic institutions, specifically affecting the academic “experiences and classroom membership of youth who speak and value AAL [African American Language]” (cited in [Vetter, 2013](#), 175). This study found that students speaking African American Vernacular English (or AAL) in classrooms invoked “issues of power and status” that “affected the formation of a respectful community” (p. 200). [Vetter \(2013\)](#) also conducted a study about race in education, gathering data in a classroom with a White teacher and a racially diverse student population. As a result, she argued that it is imperative for teacher educators to create and protect opportunities for preservice teachers to reflect on the ways that power might affect teaching methodologies, and how they approach their students.

Similarly, nationality and linguistic background play a significant role in positioning. [Maringe and Jenkins \(2015\)](#) noted that international students’ self-perception and agency was inhibited by not having an established stance to voice personal concerns they had about the university (p. 622). These perceived “constraints” were influenced by students’ vulnerabilities, which included anxiety about being othered, being marked as non-native speakers, and a lack of places to voice concerns about critical issues affecting them. These concerns are important in that they reflect how the international students are positioned (or feel they are being positioned). In turn, this influences how these students position themselves. This idea of the everyday “doing of language” ([Vetter, 2013](#), p. 174) influences a person’s sense of membership within a community, which is inarguably less accessible for students with different linguistic backgrounds than students who represent a linguistic or cultural majority.

Positioning and corporeal dynamics

[Roelvink and Zolkos \(2015\)](#) considered the “affective turn,” emphasizing the increased popularity of the phrase in relation to “the renewed interest in the category of experience, especially, though not exclusively, in terms of its corporeal, non-conscious and non-verbal dimensions” (p. 5). Positioning Theory is an ideal vehicle for exploration of non-conscious or dysconscious experiences (e.g., “dysconscious racism” [[King, 1991](#), p. 133]). Very often, as is articulated specifically in many articles already cited, research participants are unaware of the misperceptions, misconceptions, and biases that impact how they perceive others, how they perceive being positioned by others, and how they self-position. [Parrott \(2003\)](#) posited that “emotions often establish a position that is defined relative to other persons’ positions” (p. 31). Positioning is, therefore, almost always a subconscious response. Posthumanism’s attention to the corporeal and non-verbal aspects of positioning is particularly useful in uncovering these implicit positions. This is a main tenet of Positioning Theory—to make visible what can easily be dismissed, or missed altogether. A significant number of studies in this field focus explicitly on how to become aware of how people position others and themselves.

As previously observed, positions are not static and unchanging. A fundamental aspect of Positioning Theory is the dynamism of human relationships. Positioning Theory attempts to capture the ways that positions are unstable and shift over time, place, and social context. Similarly, [Roelvink and Zolkos \(2015\)](#) note that scholarship on affect has disputed the concept of a human as a “singular, cohesive, and bonded unit” that could be “characterized by relative stability over time” (2015, p. 7). In one such example, [Tanghe and Park \(2016\)](#) use an example of two research participants who “transformed their preconceived notions

that affected their initial ways of positioning one another" (p. 11). This demonstrates the fluidity of positioning, where perception shifts and can be affected by a myriad of things, which alter how people perceive and position others and themselves.

Positions are not simply relational; they have significant meaning regarding actions within a context, requiring knowledge about complex social interactions, and an understanding of how a person's position will "affect what happens in particular contexts" (Rainville and Jones, 2008, p. 447). Positioning Theory, and the role affect plays, are important because metaphorical, subconscious positionings impact self-perception. For example, Hazari et al. (2015), remark that how students feel they are being positioned can affect how students themselves access particular identities. Gee (2011) argues that when people express themselves they are composing a version of reality, both about themselves and their worlds. Rainville and Jones (2008) expand this sentiment, arguing that sociality is not made in isolation "but instead is affected by the actions of others" (p. 440). Discourse reflects reality as it is perceived and felt through affect and the body.

Conclusion

The phrase, "There is nothing as practical as a good theory" is attributed to psychologist Lewin (1943, p. 118). The purpose of theories, particularly those that are analytical and exploratory rather than predictive, is to be utilized in some way. In this regard, when applied to data, posthumanism and Positioning Theory have the potential to surface positions that may go unobserved or unexcavated. Certainly, any number of articles could be written about differences or disagreements between discursive psychology and posthumanism. But, as noted in the introduction, our intent is to ask how theories may be applied in a potentially transformative manner.

Traditionally, posthumanism and Positioning Theory have originated from different disciplinary fields and scholarly perspectives. We have attempted to consider what each of these concepts might have to offer the other. Specifically, Positioning Theory can benefit from strains of posthumanism thought in encouraging or enabling scholars to more thoroughly explore embodied and nonhuman aspects of positioning, and how such dynamics function in terms of storylines, rights, duties, and identities. These embodied aspects of posthumanism and Positioning Theory are both connected to affect and the underlying felt sense that shapes understandings of ourselves and interactions with others—whether those others are animals, humans, machines, or technologies. The posthuman project to bring attention to a myriad of others from animal to artificial intelligence challenges positioning theorists to move beyond human-to-human speech interaction to other forms of positioning such as that between artifacts and people (McVee et al., 2021). Particularly as represented in studies in literacy, Positioning Theory brings an analytic specificity to identifying and uncovering often implicit positions of which people are typically unaware. Given the work already carried out across many disciplines by positioning scholars, Positioning Theory can provide analytic means to examine data and real world interactions.

Posthumanism and Positioning Theory explorations offer affordances to look beyond binaries to open up opportunities. For example, researchers can explore multiple positions around race and racism instead of only two positions: racist/anti-racist. Such investigations can allow for clearer delineations and practices to understand processes that can move people toward a desirable outcome, such as becoming anti-racist. By bringing positions to the surface, and identifying related positionings, these theories can leverage their strengths to assist researchers in analysis. With regard to education, it is especially important that, once identified, negative impacts of positioning might be mitigated or reshaped through other actions and interactions, particularly where harm has occurred or is occurring as a result of positionings. It is here that the potentially transformational power of Positioning Theory and posthumanism are revealed. Simply put, negative impacts of positions cannot be addressed until they are identified. Once identified educational practices, processes, and interventions can be considered to bring about changes. Considering these two theories for their synergistic power holds forth the possibility of offering literacy scholars new tools to transform their understanding of positions, positionality, and positioning.

In order to make a consideration of literacy and social space more accessible, memorable, and tangible, imagine we shift our imagination of a central image in theories and discussions of literacy. Imagine this shift involves seeing literacy and its relationship to the classroom differently. In this case, we picture the classroom not as an inert “container” of children, a teacher, and materials, but rather as a city. The classroom-as-city has of course all kinds of movements in it and across it: movements of trucks, motorcycles, bodies, animals, ambulances, natural gas, water, and sewage. Busses and commuter trains traverse the city’s landscape, and endless Amazon trucks skirt from building to building, along with GrubHub cars and pizzas stacked in insulated carriers on the back of scooters. The city is in constant movement and change, and yet there are parts that seem durable over time, being made again and again. Different languages are spoken and written in different regions of the city and are often juxtaposed on digital monitors and posters throughout. Every day, people flow into the city and out—people who are classed, raced, and gendered in the experiences of their homes and perhaps differently in their interactions in the city. During the day, some of these people go to the same spots at lunch or after work—parks, bars, coffee shops. These spots become familiar and feel like places of respite. At dusk the city changes again, and yet again at night.

Over a decade ago, we critiqued the “classroom-as-container” model of conceiving of learning (and schooling) and proposed instead the constructs of “learning-in-place,” “learning trajectories,” and “learning networks” (Leander et al., 2010). Re-imagining the classroom as a city moves us into considering places (e.g., the bar), trajectories (e.g., commuting) and networks (e.g., bus routes). Perhaps more importantly, such a transition in image and imagination helps us to consider the constant movements and energy of making and remaking social space, and also consider the intensive heterogeneity of the actors who contribute to this ongoing production of space—vehicles, humans, materials of all kinds, and of course, texts and our practices with them.

One of the challenges of relating literacy studies to theories of social space, and especially to those “post” or critical of modernity, is that, like any field, literacy theory does not float free from its own history and practices, including research methods. The ethnographic turn in literacy studies (e.g., Heath, 1983; Street, 1985) brought with it a powerful focus on the socially situated meanings and uses of literacy, which was powerfully marshalled, for instance, into the development of the New Literacy Studies with its critique of an “autonomous” view of literacy (Street, 1987). Still, nearly four decades after the ethnographic turn, the field of literacy studies is still uncertain how to formulate an anthropology of postmodernity. How do the assumptions of ethnography hold up for postmodernity and its entangled, flowing social spaces? How are assumptions about the distinctions between local and global, bounded views of particular “settings” and “communities,” and the work of the lonely ethnographer, embedded in her focal “research site,” constraining for an understanding of what literacy is and what it does? Can we have a literacy studies that is at once “ideological” (Street, 1987)—entirely infused with critical considerations of power in discourse—and yet also not parochial or locally mundane?

Another present challenge of more fully realizing the potentials of critical, postmodern spatial theory in literacy studies is the fascination or even fetishization of method within educational research (St. Pierre, 2011). In the case of spatial theory, the attachment to method can run two ways—either in a search to create a settled “spatial methodology” for the field, or in the tendency to not fully engage spatial theory because such a methodology is not readily evident. These prevailing modernist tendencies can envelop a more liberating engagement with the concepts and theory in their own moves to unsettle structures, codes, and singular entities. As postmodern spatial theory is relationally conceived, and as it engages the multiple and shifting relations between people,

discourses, and things, the desires to code, fix identities, stand outside of, and create a priori boundaries as embodied methodological practices in qualitative research constrain how we might embrace the complex relationalities of social space in its reproduction and transformative becoming.

Yet another challenge for a more complete appropriation of the “spatial turn” in the social sciences and humanities (Soja, 1996) has been the centrality of a discourse-based ethos within the critical corners of literacy studies. It may seem ironic to claim that discourse—with its roots in sociolinguistics and critical social theory—could be made too central within the domain of language and literacy studies. Still, for spatial theory, a key question concerns how the material, embodied world comes into contact with discourse and is shaped by discourse, without reducing the material and embodied world to texts or sign systems. A related challenge is how we might think spatially about the material-discursive world without reducing social spaces to metaphor (another discursive framing), since the field of critical social science is already rife with spatial metaphors (e.g., center/periphery, location, place, boundary, marginalization, intersection). Studies of “third space,” for instance, while drawing richly from critical and post-colonial theory (e.g., Bhabha, 1994) can sometimes tend to treat social spaces metaphorically or as entirely discursively produced, even while taking up questions of bodies, identities, and power. In contrast, Hirst (2004) offers a rich analysis of hybrid/third space, describing the power relations in a second language Australian classroom where the teacher was an Indonesian national. That material spaces, their design, and bodies participate in the production of discourse is not in question. The question concerns how bodies, the material world, and material spaces exceed our means of interpreting sign systems in their capacities to enter into socio-material relations. How is materiality not like discourse, and yet enters into relationship with it in the production of social space? For literacy scholars, how are the meanings of signs and texts, as well as their affects, entangled with material bodies of different sorts? These are pressing and important theoretical questions for spatial theory in its development within the field, some of which are being currently considered in adjacent fields such as affect theory and studies of new materialism.

Some key contributions to literacy studies of spatial theory

Despite the challenges and limitations considered thus far, as well as others, spatial theories have made important contributions to literacy research. These contributions are still changing and growing. Without offering a complete review, we would like to synthesize a few types of contributions that have influenced the field and of course our own work as part of it.

First, spatial theory has given new insights into a reconsideration of boundaries within literacy research, with importance for methodology, but also for theoretical questions such as the distributions and movements of identity and social practice. Because critical and postmodern spatial theories begin from the premise that boundaries are produced and reproduced in social-spatial life, rather than epiphenomenal to social life, then the question of boundary-making is brought to the fore. Contextual constructs such as “out of school” come into question in this modality and may shift to become considerations of how the boundaries of “school” and “out of school” are actively made, disciplined, and disrupted. In this sensibility, boundaries become perhaps more important, as the spatial shapes the social and the social shapes the spatial but are considered as actively produced rather than as a backdrop for something focal (e.g., the “literacy event”). Issues relevant to boundary (re)production, transformation, and the hybridization of overlapping boundaries within literacy research include questions about identity, about contexts for literacy, and about our broad sensibilities concerning the “virtual world” or “online world” and its relations to the “offline world” or “meat space.” A starting point for social spatial theory is not to begin with what seem to be naturalized or given boundaries, but to begin with an analysis of the forces, materials, and processes that produce boundaries and/or disrupt them.

For critical literacy studies, the spatial analysis of boundary-making can offer a significant shift of thinking beyond the individual and her experience and toward entanglements with the social world, all while not resorting to macro structural analyses. Ultimately, for critical theory, such analyses may serve to produce means of opening up and transforming boundaries of identity, literacy, and learning, when these boundaries themselves are critically appropriated as more than mere metaphor. Sheehy (2004) describes the tensions that were created in a seventh-grade classroom as students engaged in political action relevant to their proposed school closure, examining how their activity traversed boundaries and created “in-between spaces.” Dixon (2011), drawing on Foucault’s approach to disciplining space-time, demonstrated how gaze and the organization of school space were accomplished for power/knowledge in post-Apartheid South Africa. In this case, the relations between national surveillance, oppression, and spatial enclosure and the local geography and practices of the school are accomplished with a chilling synchronicity. Finally, Nespor’s (2013) incredible analysis of spatial relations in an across an urban elementary school, based on 2 years of ethnographic fieldwork, investigates, among many other issues, the school’s collaboration with business enterprises toward refashioning classrooms into business enterprises, the children’s efforts to make sense of the scheme. Nespor relentlessly opens up the boundaries of “the classroom” to examine webs of social-spatial relations involving school division, regional economics, parental concerns, popular cultures, racial politics, urban development efforts, and other forces.

Second, literacy scholars have used spatial theory broadly and theories of place more precisely to engage in research and development with liberatory, humanizing aims. This work takes seriously the qualities of different kinds of places and how places shape experiences. Sometimes inspired and informed by phenomenology, place-inspired research is also often focused on the capacities of educators and children to transform school or institutional spaces into places that matter and that offer growth. Some place-oriented research has actively engaged children in processes of textual and material place-production. For example, an ongoing project by Comber and colleagues (“Urban Renewal from the Inside Out”) has engaged children with university students from the fields of architecture, communications, and literacy students to redesign an area of the school grounds in a poor suburb of

Adelaide, South Australia (Comber and Nixon, 2008). These forms of local spatial transformation are a means of creating a critical literacy pedagogy that is more fully embodied and spatially infused. Because of its engagement in the nature of experience, place-inspired research provides a natural bridge to more recent work in effect theory and literacy (Boldt, 2021; Hollett and Ehret, 2017; Niccolini, 2019), which is concerned with the different kinds of affects produced when texts and bodies of different sorts come into contact or relation with one another.

A third key contribution we wish to highlight concerns an understanding of mobilities in literacy research as conceived through spatial theory. As discussed in the opening regarding the expansion of ethnography within the postmodern, toward something like “connected ethnography” (Hine, 2000; Leander and McKim, 2003) or another formulation, mobilities studies are given to thinking about practices, texts, bodies, and technologies in their circulations. Such circulations may include a given “situation” or context, but situatedness is often considered as a temporary arrangement or assemblage. Mobilities research in literacy has drawn variously on critical spatial theories and also on social theories and philosophy taken up by spatial theorists, including Actor Network Theory (Brandt and Clinton, 2002; Leander and Lovvorn, 2006), Deleuzian rhizome theory (Eakle, 2007; Hagood, 2004; Leander and Boldt, 2013), embodied media composition (Ehret and Hollett, 2014; Vasudevan, 2010) and rhythm-analysis (Leander and Hollett, 2017). In an important contribution to mobilities research in literacy studies, for example, Brandt and Clinton (2002) provoke: “might something be lost when we ascribe to local contexts responses to pressures that originate in distant decisions ...?” (p. 338). Drawing on Actor Network Theory, the researchers reconsider Besnier’s (1995) study of the on the geographically isolated, subsistence-based Nukulaelae people, who would wear Western-style tee-shirts “bearing risqué slogans in English” (p. 343). The slogans did not enter into the textual/meaning-making practices of the Nukulaelae, and yet the tee-shirts did. As a result of their reconsideration, Brandt and Clinton (2002) expand a mobilities mindset, invoking a “thing like status” to literacy to consider how the material dimensions of literacy travel across time and space, integrate, and endure. In this way, the global and the local become situated in movement and practice rather than being captured in representations or static backdrops.

Reading across the key contributions described above, and considering others too numerous to discuss presently, it would be difficult to describe the many possible expansions and revisions of literacy studies in their contact with spatial theories. However, one insight that we have gleaned from this effort is that the value of spatial theories will at least in part be determined by their capacity to contribute interpretive texture, “layers,” nuance and insight to the qualities that are already made present in (critical) qualitative research. Inspired by such textured, layered approaches, and in order to further illustrate an analysis of social space and schooling, we turn now to an examination of social space in the recent history of schooling during the Covid-19 pandemic.

Popular discourses of school space and Covid-19

Our approach in the following is to consider the social spaces produced in and around “schooling” during Covid as fully relational, and as produced through conceptions or intentional designs of space, perceptions or discourses of space, and lived experiences of space (Lefebvre, 1991; Soja, 1989, 1996). Within “lived experiences,” we are especially interested in the affective dimensions of the experience of living in and through the period of Covid-19, and “doing school” during this period. The media we draw on in order to record and reflect on the productions of space during Covid-19 were published popular press and the social media network TikTok from March 2020 to June 2021.

We have chosen these media because they illustrate experiences of being a teachers, students, and parents during Covid-19, and also reflect discourses around remote schooling that developed at this time. From the popular press, we searched out profiles, editorials, and interviews that depicted or addressed the experiences of remote schooling. While completing this survey, we noticed that while teachers, and parents were well represented, the perspectives of students were harder to find. When the experiences of students were depicted, they were most often mediated through an adult interviewer or journalist and published for a presumably primarily-adult audience. We therefore widened our search to include TikTok where we knew many students—as well as parents and teachers—had participated in discourses on schooling during Covid-19. We coded these media and selected telling examples of expansions the boundaries of school, spatial reproduction and simulation, embodied experience and the effects of space, and critiques, resistance, and transformations of school space.

In the following, we describe three different “variations” of social space that arise out of our analysis of these media. We intend these variations as different productions of social space that are reflected in the media we have studied, as well as partially produced through them. For each variation, we consider some of the relational dimensions of social space, including how the embodied, material world, discourses, power relations, agency and affect are interconnected and co-constructed in the production of social space. We do not consider this analysis nor these data to be a “complete” rendering of social spatial relations of schooling during Covid-19. Rather, our goal is to use them to illustrate the dynamics of social space, and the uses of spatial analysis to consider how experience, space, literacy, and discourse are co-produced. We also aim to make evident how qualitatively different experiences of school (and literacy) are spatially produced—that space not only “matters” but is also co-constituted with unique, distinct qualities of experience.

In the first variation, we detail productions of school space during Covid-19. We trace how school boundaries were expanded as classrooms were physically and affectively reproduced in homes. Next, we look at how conceptions of school, power relations, teacher decisions, and technology design interacted to simulate hyperreal classroom spaces online. We then analyze discourse around cameras to uncover ways student presence in these spaces was produced, measured, and disciplined.

The second variation traces the affective shortfalls of school space in remote learning. We examine accounts of mismatches between the hyperreal simulations of school online and embodied experiences being students, teachers, and parents during remote schooling. We consider affective impact these mismatches had on people subjected to them. We then turn to TikTok posts in this variation to illustrate experiences of remote schooling and its shortfalls, and also to trace how discourse on the platform helped shape collective understandings.

In the final variation, we focus on manifestations of student agency. We look to TikTok for collectively authored critiques of school space during Covid-19. We also examine subversions of school boundaries and collective acts of resistance on the platform. Finally, we detail accounts of students and teachers forming empathetic relations and collaboratively reshaping their remote school, and consider if these episodes point to possibility for the production of more humane school space.

Variation 1: physical, affective, and hyperreal productions of school space during Covid-19

The physical and affective reproduction of school space at home

In media we surveyed, teachers sought to replicate elements of their classroom by gathering school materials and rearranging furniture (Hadden, 2020; Hackman, 2020; Dominus, 2021). These redesigns of teacher's homes seem to have functioned not just as physical, but affective reproductions of school space. A chronicle of a day in the life of Matthew Bordello, a second-grade teacher working remotely illustrated this process (Hadden, 2020). Bordello's conception of his class had been deeply tied to physical space. "Our community as a classroom is very much on being together and being able to share things with each other and build off together in a group" he argued. The transition to remote learning could have devastated this community and Bordello's self-efficacy as a teacher. However, by rearranging his bedroom he recreated some of the routines and feelings of this in-person community. He made space for art supplies, books, and hand drawn copies of the "classroom agreement posters" that hung on the classroom walls. While he his workspace/bedroom "might seem chaotic to others" it was the "ideal environment for keeping his class focused" which let him "recreate a sense of organized chaos in his virtual classroom." For Bordello, and he believed, his class, feelings of order were restored.

Students and families reproduced school spaces at home as well. One P-12 private school, displayed this work in a series of interviews with remote students of different ages (In their own words, 2020). The interviews were punctuated with photographs (see Fig. 1) of the subjects sitting at large desks in bright bedrooms with stacks of books, notepads, and a laptop or tablet around them. While taken in different houses, they share striking physical and qualitative uniformity, seemingly curated by the same schooled expectations. The consistency of the images parallels the interviews themselves. Each student expressed some melancholy about isolation, but they mostly described their—quite similar—homeschool routines and conveyed of self-confidence and comfort. These accounts imply that through intentional redesign of home space and activity physically and affectively expanded the boundaries of school space into the home.

Hyperreal school space on videoconference platforms

The social space of schooling was not simply relocated during Covid-19. Rather, we argue, the displacement and re-placement of school qualitatively changed its space. In the media we reviewed, we can trace how simulations of school—or perhaps more accurately, of conceptions of school—produced hyperreal school spaces. Baudrillard (1994) describes the hyperreal as "the simulation of something which never really existed." It is the representation or reenactment of something which had previously existed only as an abstraction. Baudrillard points to the depiction of medieval Europe in Disney World, as an example—it doesn't simulate any place that existed in history, but a preexisting, essentialized conception. Similarly, remote schooling arguably simulated conceptions of school rather than actual school spaces. Certain "school-like" qualities, such as teacher-control and focus on attention and evaluation were more intense than they had—or ever could have—been in physical classrooms. Across the media we surveyed, conceptions of school, teacher actions, and the design of videoconferencing platforms could be see coproducing these hyperreal school spaces.

Fig. 1 Screenshots of photos in a school online publication of students working from home. Photos taken from a school publication of a twelfth and fifth grade student of working from their homes.

Bordello turned to various Zoom features to simulate his second-grade classroom (Hadden, 2020). He used breakout rooms for different ends, including sequestering students “when their distractions affect[ed] others”—a move reminiscent of timeouts. The hallway or corner where students Bordello had sent students for timeouts was thus simulated on Zoom. In some ways however, these breakout rooms were more “timeout-like” spaces than could have existed in a school. They were more isolated. A child could hear and see her classmates while sitting in a corner, but she would have no access to the Zoom meeting while in a breakout room. Teacher control was also heightened. In person, a student could resist timeout and still affect the rest of the class by making a ruckus or walking back to the group, while on Zoom, she had no recourse. The timeouts enacted in breakout rooms were in these ways hyperreal.

Breakout rooms seem to have been made into hyperreal instructional spaces as well. English professor Nguyen (2021a) argued this feature not only allowed the replication of classroom discussions, but helped make them “better than those of the in-person era.” When teaching in person, he prompted students mid-lecture to gather in small group for discussions. Teaching remotely, he put them into breakout rooms. He saw the latter structure as better suited to his goals because it was “simple to arrange and lack[ed] the cacophony” of live discussion. As with the virtual timeout, distractions that could accompany proximity were stripped away. Students no longer had to move or look around to form groups—transitions were streamlined to pushes of buttons. While buzz and bustle of other groups had been present in the classroom, on Zoom students could only see and hear their groupmates. In some ways, these breakout rooms were therefore distilled for focus on instructional activity beyond any classroom.

In a few of the cases we reviewed, teachers’ changes to videoconference settings helped produce essentialized school space. In a newspaper profile (Hackman, 2020), a sixth grade teacher described remote teaching as “all the same stuff I [did] in class ... I just needed time to figure out how to translate those skills virtually.” One way she did this was by “eliminat[ing] the class chat function, allowing to only send messages to her.” This choice constrained student discourse in a “school-like” manner, which bore striking resemblance to the Initiate-Respond-Evaluate (IRE) model that has long dominated US schools (Nystrand, 1997; Wilkinson et al., 2015). Following an IRE model, student utterances are directed, heard, and evaluated by a teacher. No matter how rigidly their classroom followed this structure though, students could circumvent expectations and surreptitiously communicate without the teacher’s notice by passing notes or sharing whispers. In this virtual classroom however, all communication was witnessed by the teacher and subject to evaluation. The videoconference was not a replication of an in-person class, but a hyperreal “school-like” simulation.

Discourse on cameras and student presence in hyperreal school space

Perhaps the most widely written about videoconference feature during the pandemic was the camera. Arguments for and against mandating students to keep their cameras came up repeatedly in our survey popular press (Hackman, 2020; Nguyen, 2021b). This discourse revealed contested understandings of what it meant to be “present” in a remote lesson. By examining this discourse, we can uncover ways in which student presence was produced and disciplined in the hyperreal school space of remote learning by technology, school policy, and student and teacher actions.

Mandates around cameras seem to have been widespread during Covid-19. In a survey of American K-12 educators, 77% stated their students “must” keep their cameras on (Will, 2020). Many of the arguments for these requirements centered on accountability and attendance. Some teachers maintained live video helped them keep the class engaged because they could hold students accountable (Hackman, 2020; Burney, 2020; Will, 2020). One assistant superintendent bemoaned that before her district’s camera mandate, students logged into class to be counted as “present,” right before “turning off the camera and walking away” (Burney, 2020). After the mandate, she claimed her district achieved “95% participation.” What she meant by “participation” was not clear, but a teacher from her district revealed in the same article that she gave participation grades based on who kept their cameras on “just like when I [took] attendance each period at school.” According to her school’s measures of accountability, grades, this teacher’s students participated in her lessons simply by visibly attending them.

The understandings of student presence in these arguments were notably thin. Discussion, collaboration, creation, and reflection were all absent. Many students undoubtedly did all of these activities in remote lessons, with or without their cameras on, but they could only be counted—or held accountable—as present if their teachers could see them. Presence was thus passive and arguably deadened. This dynamic echoed critiques forwarded by Freire (1972), Davies and Bansel (2007), Nespor (2013) and others that schooling in capitalist and neoliberal societies understand students as objects to be acted upon. In classrooms, students were often not expected to act but to receive instruction and present themselves for accountability. In remote lessons, this dynamic intensified. Physical attendance in which students had sat in classroom and regulated their bodies was simulated by videos of their faces—ignoring their embodied and affective experiences. Student subjectivity, long overlooked in school spaces, seems all but irrelevant to student presence in these hyperreal classroom simulations.

Variation 2: affective shortfalls of hyperreal school spaces and remote learning

Anxiety and the mismatch between the presentation and experience of remote school

Attempts to simulate school space during remote learning appear to have taken affective tolls on some teachers, students, and parents. Many accounts of remote learning detailed disconnect between how teachers experienced teaching during Covid and how they presented—or hoped to present—themselves. Some teachers felt anxiety and a loss self-efficacy when navigating this mismatch. In a longform article tracking the year of an AP World History class, the teacher, Ms. Everett-Kennedy, described school building was a “community-ordained safe space” and her classroom a “locus of control” that was a “near sacred space in which she

excelled" (Dominus, 2021). Extracted from these spaces, she felt these senses of order, community, and self-efficacy disappear. She attempted to regain them in part simulation. She tried to appear energetic on Zoom, as she had been in person, and to keep clutter hidden from the camera so she could project an image of order and control. But struggles over the course of the pandemic prevented her from maintaining this image. As one student described her, Everett-Kennedy often came to zoom with her "hair in that messy ponytail, tired eyes, that bottle of Diet Coke always beside her." While this student found the presentation relatable, it fell short of Everett-Kennedy's self-expectations. Frustrated by her inability to support and connect with students as she had in previous years, and regain control over her life and image Everett-Kennedy went through bouts of anxiety and disappointment, saying she expended "more and more energy to fight off her sense of failure."

Like their teachers, some students felt anxious about presenting themselves in videoconferences. They carefully considered what was displayed. Three of Everett-Kennedy's students were described angling their laptops to hide messes in their rooms (Dominus, 2021). Anxiety about self-presentation was particularly pronounced in one student, Charles. According to the profile, Charles was a straight-A student who was "used to entertaining his classmates but also impressing his teachers." As a high-achieving Black teenager he had felt pressure to live up to the high expectations of his mother while confronting a racist society and "proving these stereotypes wrong," but he felt he was on track to live up to these goals. However, when the schoolhouse closed for the pandemic, Charles began struggling with mental health and fell behind on school work. He was determined to hide these challenges. Always a "skilled performer," he became not only an actor, but a set-designer to simulate the role he had filled before the pandemic. He set up "his personal stage [in] his bedroom, where he'd hung LED lights and a tapestry with a design that evoked some graphic novel's envisioning of another planet." The journalist notes that "from that room, Charles projected the image of young man wildly amused and amusing." This projection was hyperreal, however—it showed not who Charles actual identity or experience, but how he believed he should be. The pressure to uphold this image was a drain on him. As his affect and experience worsened, this anxiety grew more intense, as did his evasions from support. He was ensnared in a devastating cycle. By the winter of 2020, Charles was convinced "failure was his destiny."

Missing connections and affective depletion in remote school

Students and teachers in the media we surveyed repeatedly described videoconferences as not-quite approximating classes in person. They often foregrounded what was missing—physical proximity to others and associated feelings of energy. This sense that remote learning, as a simulation of school space, was missing key elements it *should* have imbued accounts with effects of disconnection, longing, and depletion.

Teacher-student conversations over videoconference were often characterized as strange or awkward (Dominus, 2021; Blum, 2020; Nguyen, 2021b; Osman, 2020; Hackman, 2020). Forming relationships became more challenging. Teachers lamented talking to "a sea of black squares" (Nguyen, 2021b). Students were more reluctant to be vulnerable—"it's hard to believe someone you only met through a screen" one high schooler explained (Dominus, 2021). Physical distance weakened the affective connection between student and teacher. Both teachers and students described shifts in group affects as well. Class discussion was subdued (Nguyen, 2021b; Blum, 2020) and students had felt energized by in-person gatherings, felt drained after videoconference lessons (In their own words, 2020; Dominus, 2021).

Many of these accounts related feelings of depletion with strained connections between classmates and teachers and students and their lack of physical proximity. Anthropology professor Blum (2020) theorized this dynamic in more detail. When considering why she felt exhausted after teaching on Zoom, she concluded "it is because videoconferencing is *nearly* a replication of face-to-face interaction but not quite [that] it depletes our energy." While Zoom allowed her class to see one another's faces and hear their voices, Blum argued it did not enable "harmonized posture," "coordinated breath" or eye gazes that "communicate information." Humans, she claimed, were "delicately attuned to each other's complete presence" and so they read these nonverbal cues to support conversation in person. In many ways, videoconference made presence thinner—for example, one could not tell where another was gazing. While these changes were subtle, they were also meaningful. They left conversations halting and labored which Blum argued, which led to feelings of frustration, depletion, and a longing for more free-flowing human connection.

Techno-social discourses of student affect and mental health during Covid-19

By surveying TikTok clips with hashtags related to remote learning, we traced lines of student discourse around remote learning, affect, and mental health. Thousands of posters, including many middle school, high school, and college students uploaded clips documenting their experiences during the pandemic. The design of TikTok, where users could easily edit and repurpose audio and video from existing posts, enabled the emergence of multiple lines of discourse where thousands of students watched, commented and posted response videos to one another's clips. Though physically isolated, students were able to collaboratively publish and interact with techno-social discourses around remote learning and its effects on them.

One particularly striking motif that was seen across many TikTok pound we found was panic attacks. One TikTok which was liked over two million times showed an adolescent girl crying and breathing hard while her parents look at a laptop. Text came up over the video that read "the chem final my sister has been taking for 3 h didn't save" while pre-existing audio played of a woman repeating "just breathe." Even with her family in person, trying to help address the issue, inadequate technology and the demands of remote schooling overwhelmed this student. Many viewers could relate—the most-liked reply read "the crying and pacing while parents attempt to fix it resonates with me."

Increasing lists of assignments and problems come up in many videos. One popular post, pictured below, was representative. The camera faced an adolescent laying **their** head on a desk. Audio taken from another TikTok played where a robotic voice rapidly

listed assignments, tasks like “clean your room” and “take a shower,” invectives such as “work until it hurts” and questions such as “does he still love you?” and “what happened to you?” Words such as “due at 11:59” and “missing assignments: 35” flashed on screen. Not quite obscured, the adolescent’s head slowly sank, as though pushed down by the words above them (see Fig. 2). Clips such as these evocatively illustrated their feelings of depletion, and at times, depression. Like the teen shown in this TikTok, many adolescents appeared to fall further into hopelessness and isolation as the demands of remote learning cascaded upon them.

Notably though, the students who posted and viewed these TikToks were not entirely isolated. While physically distanced, the views, likes, replies and response videos demonstrate they saw and heard one another. Their techno-social discourse allowed remote students to share in, and, to an extent, shape their affective experience during the pandemic.

Variation 3: critiquing, resisting, and transforming school space

TikTok critiques of the production and boundaries hyper-school

From what we surveyed, TikTok posters didn’t only aim to document remote schooling, but to spoof it. Many popular videos drew humor from unbridgeable gaps between the experiences of remote schooling and the images the uploaders had hoped to present. While some of this comedy was self-deprecating, it was often pointed toward the absurdity of remote schooling and the demands it put upon them without regard to their conditions and experiences in reality. These clips may therefore shed insight not just into how students, teachers, and parents experienced the emergence of hyperreal school space of remote learning, but how they critiqued it.

A recurring theme was sights and sounds accidentally recorded during virtual lessons. In one clip, a woman sat on a rug and explained “I’m sitting on the floor, next to my children’s desks ready to mute and unmute their Zoom class,” out of view from their Chromebook cameras. She said with a wide smile that while her children knew how to unmute themselves, they often “do it at the wrong times and everyone can hear me screaming in the background.” She thus subverted and mocked the expanded boundaries of school space into the home. Remote schooling compelled her to simulate scenes of home-school life that, implicit in her telling, can only be created through extreme and surreptitious measures. What’s more, even if she succeeded in curating a scene for Zoom school, her family’s *actual* home-school would fall short of the presumed standards. If everything was going well, after all, why would she be screaming? She could not meet the expectations she assumes the teacher and/or other families have for remote learning, so she had to hide, crouching on the floor for entire lessons. The demands of simulating homeschool appeared harmful and absurd.

Many TikToks posted by students documented their struggles with staying, or appearing to stay, present during virtual lessons. One widely-viewed post panned in on a square in a grid on a Zoom screen where a cat sat alone staring at the camera while a man lectured monotonously in the background. The caption read, “I forgot to turn my camera off when I went for a walk and my friend sent me this she was there for like 15 min #catsoftiktok #zoomschool #fyp.” This text implied embarrassment not for walking away from the lesson, but for leaving the camera on to capture this humorous tableau. The poster seems to have taken it for granted that the expectation that to sit still at her computer for the entire lecture was unreasonable, or at least unimportant, but *showing* she left was a breach of social norms. Several comments, where users shared fears that this could happen to them, pointed to the same conclusion. It was impossible to meet the implied expectations of this new school space, so they instead hoped to conceal themselves. The possibility of revealing their activity and movement appears to have filled many students with anxiety and fear. By

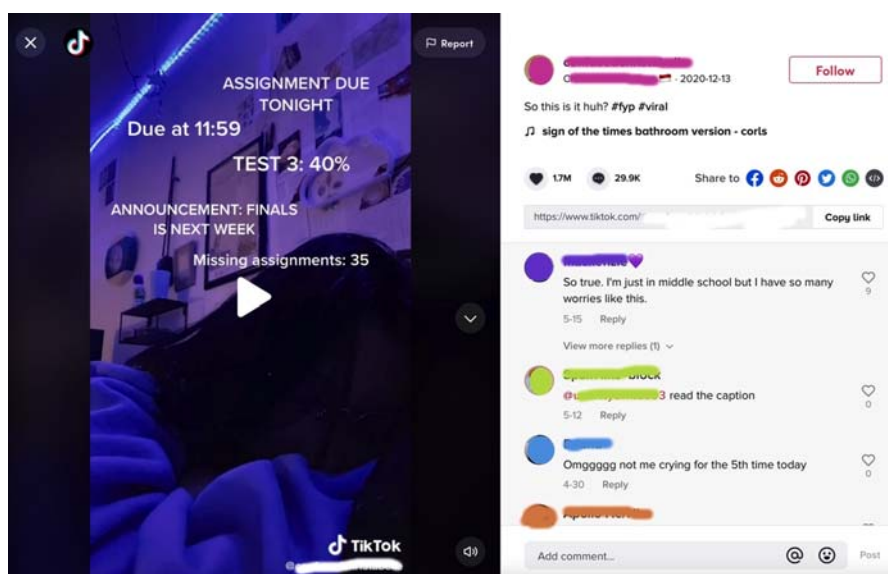

Fig. 2 Screenshot of a remote student’s TikTok post and user’s comments.

sharing these experiences and affects, these TikToks implicitly critiqued remote learning. Could such empty simulations really be worth this stress?

Resistance through play: student challenges to school space on TikTok

TikTok posts not only revealed critiques of the social space of remote school, they propagated challenges to it. Students posted hundreds of clips that documented pranks and hacks that altered remote learning spaces. Many clips appeared explicitly designed to instruct others how to replicate these tricks. They were often saturated with referential humor that evoked aspects of youth internet culture and seemed to invite viewers to respond. The techno-social discourse of remote student TikTok thus seems to have cultivated acts of resistance to remote learning that were collectively-designed by students spread across the world and physically isolated.

Some of the most-liked clips we found of this genre were pranks where students subverted expectations of their remote lesson space by collaborating and manipulating the technology. For instance, one clip, captioned, “April Fools on our professor #aprilfools #fyp #zoomschool,” showed a young woman recording and laughing at a zoom screen where a professor mumbled “what’s going on ...” as over a dozen users logged into the meeting with the same default photo of his face and name. The students disrupted their remote class by wielding the technology and their professor’s own name and image against him. Other pranks were less reliant on videoconference features. Several clips showed teachers interrupted as their class suddenly breaking into synchronized dance routines across the grid squares on the screen. These pranks were likely shocking not just because they were unexpected, but because they clearly implied the class communicated and coordinated without the teacher’s knowledge. While students were highly surveyed in many remote lessons, these pranks demonstrated they could still surreptitiously collaborate, plan, and play outside of them. Posts tagged with #schoolhacks or #collegehacks, or #studhacks were. Some of these videos offered advice on study habits and using remote learning technology. Others demonstrated ways to surreptitiously circumvent teacher’s rules and expectations. At the time of our survey, the two most liked TikToks with the tag #onlineschool showed how to use software that hacked google-form quizzes, auto-filling all of the correct answers. Similar videos demonstrated the steps to photoshop pictures of homework to send to teachers, trick mouse-tracking programs, and set looped videos as their Zoom default picture to make it appear cameras were on.

These TikTok clips revealed heteroglossic and highly participatory discourses. Comments shared stories similar to the videos. Clips referenced one another by incorporating each other’s audio or video. They often referred to other elements of online youth culture by layering sound from viral social media clips, and working in humorous images from memes (video of a bald man vigorously eating a sandwich shows up in many of these TikToks without explanation, for instance). Through this discourse, it appears that students were able to remotely form social spaces apart from remote school, where they could then—to an extent—collaborate to circumvent and resist the boundaries and expectations of school space.

Techno-social transformation of school space

While much of the accounts of remote learning focused on struggle, there were also glimpses of how school spaces might be made more humanizing and collaboratively-designed. In some instances, teachers and students appear to have developed understanding and empathy for one another as video conferences bridged their home environments and lives. One student-teacher likened this dynamic to “a throwback to a time when teachers made home visits” (Arthur, 2021). Some teachers considered equity in a new light, realizing that some of their students homelives made schoolwork more challenging—both when school was remote and in person (Osman, 2020; Will, 2020). Students too were described as reconsidering their teachers’ perspectives after seeing and hearing their struggles over zoom (Dominus, 2021; Nguyen, 2021b). These accounts suggest that as remote schooling expanded the borders of school space into the home, it also offered at least some teachers and students more insight into one another’s lives.

On TikTok, audiences seemed fairly segregated between students, teachers, and parents. Most comments on student videos appeared to made by other students and parallel patterns held with teacher and parent posts. There was, however, also discourse between these groups. Some popular teacher posts were duets with student posts. At the time of our survey, one such duet, pictured below (see Fig. 3), was most-liked post tagged with #remoteteaching. On the right, a student’s TikTok played, illustrating the overwhelming demands of remote learning. On the left, a teacher sat silently, appearing to empathetically react to the video. This post and ones like it showed meeting of space and experience. By apposing these self-authored, affectively-imbued videos the poster not only joined the environments of her and the student, but couples their perspectives. This TikTok thus showed a space co-written by a student and teacher and reflective not just of their respective roles, but their human experiences.

In the popular press there were a few examples of elements of remote school space being similarly collaboratively and humanely produced. One middle school teacher (Osman, 2020), how her student’s use of chat helped shape the discourse and content of her zoom lessons. Chat enabled multilinear conversation, as students could simultaneously talk over speaker, type to the class in the chat, and send private messages. It allowed multimodal discourse, as students used words, acronyms, emojis, and pasted images and video-links. The teachers admitted, “I am still learning this particular language they speak in, but [my students] are quite happy to translate.” Sometimes the messages were connected to curricular content, sometimes they weren’t. The teacher explained she followed deviations from her lesson plans more than she would have in person because she sensed her students longed for the human connection it provided. A few pieces described classes collaboratively establishing norms around cameras in remote lessons. Several teachers reported telling their students to turn their cameras off or on whenever they felt needed (Will, 2020; Burney, 2020; Nguyen, 2021b; Osman, 2020; Dominus, 2021). One professor (Nguyen, 2021b) detailed she opened up to her students about her struggles with teaching to blank screen, and the class then discussed balancing their needs for privacy with their classmates and teachers desire for connection as factors to consider choosing when to turn of their cameras.

Fig. 3 A screen shot of a teacher's duet on TikTok with a student's post.

In these examples, teachers, students, and technology co-produced school spaces that were in some ways more responsive and humane than many in-person classrooms. Chat enabled new modes of communication to come into school space, many of which were more familiar to students than teachers, and closer connected to their out-of-school lives. When choosing to turn on or off their cameras, students could determine how to be present, seen, and available for in a manner unreplaceable in person. School space during Covid-19 was therefore not only reproduced, resisted, and made hyperreal. It was also transformed into spaces that could, at times, allow for collaborative and human connection.

Final thoughts

Although spatial theory to re-see approaches otherwise more familiar in qualitative literacy research, such as textual coding, observation, or discourse analysis, ultimately the values of the theory will largely depend on how it is used to bring to life the particular meanings and effects of literacy practices, texts, and discourses in their emergent relations to bodies and the material world. From the broader push of the earlier work on social space—that space matters, and that social spaces are everywhere produced—one important shift involves asking how to understand and feel the particular qualities of different types of spaces and places involving literacy and literacy learning. Our analysis of variations of social space during Covid-19 is an attempt to bring to life these qualities and affective dimensions of spatialized experience.

Among Doreen Massey's far-reaching contributions to spatial theory, she proposed three maxims for understanding space: first, as a product of interrelations, themselves constituted through interaction; secondly, as a dynamic of multiplicity in which distinct trajectories and heterogeneity co-exist; and thirdly, as always in the process of being made (Massey, 2005). Massey was fond of claiming that social space was the accumulation of "stories told so far," or an "open and ongoing production." Social space is not outside of our making of it, outside of our discourses on it, of our bodies moving through it. The openness of social space is, in the end, also much of its significant potential for social theory and for literacy studies more specifically. Spatial approaches are not merely a more robust or geographical method to "map" existing power structures; rather they open up for us how the movements of power—including those more liberating—shift and may be re-storied over time.

Doing theory requires being open to the world's aliveness, allowing oneself to be lured by curiosity, surprise, and wonder. Theories are not mere metaphysical pronouncements of the world from some presumed position of exteriority. Theories are living and breathing reconfigurings of the world. The world theorizes as well as experiments with itself. Figuring, reconfiguring ... Thought experiments are material matters.

Barad (2012, p. 207).

Would educational researchers be willing to forgo methodology for the possibility of an unpredictable future-to-come, one that is not foreclosed by repetition of the same?...What would it be like not to know what to do next, and then next, and next when one inquires?

St. Pierre (2016d, p. 3).

In December 2015, Elizabeth St. Pierre gave an invited lecture for the Literacy Research Association (LRA) titled "Post Qualitative Inquiry". In this lecture, similarly to her chapter in the *Sage Handbook of Qualitative Research* (2011) titled "Post Qualitative Research: The Critique and the Coming After", she outlines what she calls, *conventional humanist qualitative methodology*, and offers a turn toward poststructural and posthuman inquiry. The "post" in post qualitative inquiry (PQI) is a (1) questioning of the taken-for-granted assumptions of qualitative research built on the logics of humanism and a (2) imagining, inventing, or experimenting with the not-yet-known or the unknown possibilities when thinking and inquiring with post-philosophies such as postmodernism, poststructuralism, posthumanism, and others.

Philosophies, paradigms, and theories all have a grid of intelligibility according to Foucault or dogmatic images of thought according to Deleuze that make particular inquiry practices (im)possible or (un)thinkable. The (im) and (un) before these words signals a both/and logic that something can be both possible *and* impossible simultaneously. As an example, St. Pierre's (2000) discusses at length what makes a feminist, poststructural paradigm possible for inquiry and gives examples of how one conceptualizes the subject, language, discourse, agency, freedom, power, reality, knowledge and so forth *and* how and why these conceptualizations matter in the doing of inquiry. The term post qualitative inquiry was a phrase St. Pierre created to name what she'd been doing as an inquirer since her dissertation in the 1990s (see St. Pierre, 2011, 2015, 2016b, 2016c). She conducted interviews and did all the methods deemed as appropriate qualitative research only to find out that the methods fell apart, so to speak, as she tried to write about methodology and do analysis that philosophically didn't align with the poststructural theories she was writing-thinking-with.

Prior to this invited lecture at LRA, literacy researchers were already thinking-with post-philosophies in literacy education (e.g., Leander and Rowe, 2006; Kuby, 2014), but they were few and often found it hard to fissure into a community of conferences and publications venues, that was/is still operating in a think atmosphere of logical/positivist empiricism and even phenomenological empiricism which is often found in interpretivist and conventional humanist qualitative methodology approaches (see St. Pierre, 2016c, for a discussion on three empiricisms). Thus, in order to open spaces for scholars to do inquiry inspired by post-philosophies, the broader field of literacy education has to be open to paradigms that aren't considered the normal or accepted way to do research. As St. Pierre (2016d) reminds us, we made up these paradigms and research methods at one point in time anyway. Surely, we can question them and think of new ways to do inquiry.

This shifting to post-philosophies and the doing of inquiry is sometimes called the 'the material turn' or 'ontological turn' in the broader social science and humanities communities and in the discussions among what is traditionally called qualitative research methodology. Post-philosophies often focus (primarily) on ontologies (being, reality) and do so in a mutually constitutive way with epistemology (knowing, knowledge) and axiology (ethics, relationships, aesthetics), hence the neologism, ethico-onto-epistemology (see Barad, 2007; Lenz Taguchi, 2010; Kuby, 2017a). What all this means is that how we evaluative and review research that is situated in post-philosophies can't be measured against the philosophical assumptions and methodological practices and standards of logical/positivist empiricism and even conventional humanist qualitative methodologies (phenomenological empiricism) that we are so familiar with. Nor can we take a study that operates in one of these empiricisms and logics of thought and just "add ontology and stir" (St. Pierre, 2016a, p. 2). By doing this we would retain

the descriptions of human being, language, knowledge, power, agency, resistance, rationality, materiality, and empiricism that organize the ontology, epistemology, and methodology of humanism we've been taught and have learned so well. Making this ontological turn requires, to a great extent, that we unlearn and try to forget what we've been taught about the nature of things. As [Kuhn \(1962\)](#) notes, this shift, this turn is not a tweaking or extension of what is but, rather, a rethinking from the ground up, in this instance, of an ontology in which the human/nonhuman, human/material binaries are no longer intelligible and in which empiricism is no longer an epistemological project.

[St. Pierre \(2016a, p. 2\).](#)

This might be hard for literacy researchers, and educational researchers in general to swallow, as our projects are firmly rooted in epistemology (knowing and learning benchmarks, objectives, goals, standards) and I would say largely with the absence of ontology and axiology. What is an empiricism, in educational (literacy) research, with epistemology not the center focus? And what might this empiricism make possible and produce?

Perhaps many of us did not have coursework in our graduate programs on ontology, philosophies, axiologies, and empiricisms. If we didn't, we might not know what they are and what they make (im)possible or (un)thinkable for inquiry practices. This was definitely true for me and I've spent over a decade trying to read and understand why this all matters for the doing of inquiry, pedagogies, and for literacies. As [St. Pierre \(2016d\)](#) writes, this entails having to untrain educational researchers. We have to rethink and think-anew our research practices.

I doubt that our research training prepares us for the productive confusion of not knowing what "to do" when we try to straddle disciplines ... We may not even understand the language of another intellectual tradition and demean its specificity by calling it "jargon." Its research practices may not seem "scientific," and its research process may lack the over-rated "systematicity" that seems to guarantee something is scientific. In confusion, we may cling to our training, so we know where we're going and what to do next. Hence, I have come to believe that research training too often gets in our way, prevents us from recognizing the "new" that is always already there in the world, and shuts down futures that might be—an education-to-come we might desire ... research training (repetition) can stifle invention (difference) and thereby impoverish possible futures of educational research and education.

[St. Pierre \(2016d, pp. 2 and 3\).](#)

This is hard to imagine as we are the instructors for research courses and thus in order to untrain ourselves, we have to learn alongside or with our graduate students. We have to teach the courses on philosophies, empiricisms, paradigms, axiologies and experimental ways of doing inquiry in order to learn (or rather invent, create, make) the content ourselves. We have to take a risk and allow new generations of scholars to stretch us and not become defensive or reject research when it looks and feels different. As editors of journals, conference proposals reviewers, dissertation committee members and advisors, and tenure/promotion committee members we have to be open to the otherwise.

It is important to pause upfront in this chapter to acknowledge a long history of Indigenous ways of knowing/being/doing in the world, many of which intersect with the ethico-onto-epistemological assumptions of post-philosophies. Indigenous scholars, such as [Robin Wall Kimmerer \(2013\)](#), a botanist and philosopher, writes about how the world comes to be based on long histories and traditions from the Citizen Potawatomi Nation of which she is a member. Thus, the neologism PQI came into being long after Wall Kimmerer's peoples thought about the inter-relatedness of lands, plants, animals (including human), spirits, and so forth which relates to concepts such as subject, agency, identity, and language. [Kakali Bhattacharya's \(2020\)](#) article, "Rejecting Labels and Colonization: In Exile From Post-Qualitative Approaches," speaks to her pathways to de/colonial ontoepistemic orientations of research and not needing the labels such as PQI. She describes this as a process of un/learning and self-exile. Other scholars, internationally, for example, such as [Fikile Nxumalo \(2018\)](#) and [Alison Jones and Te Kawehau Hoskins \(2016\)](#) also discuss the needs and tensions of working with/in post-inspired philosophies, Indigenous traditions, and/or de/colonizing inquiry practices.

Thus, as things are named, such as PQI, lines and boundaries are drawn, and exclusionary practices happen. People try to create what counts and what doesn't count as PQI. And as this happens, PQI expands, shifts, and becomes something that was unknown before. So while many post/decolonial and Indigenous scholars might not label themselves as PQI, I find a generative space in thinking through/with/across various traditions on knowing/being/doing, especially ones that believe the world comes to be in ethico-onto-epistemological ways. My aim is not to label or put into boxes people's work. I prefer a broader phrase "post-philosophies and the doing of inquiry" (although I realize what gets labeled as post-philosophy already draws lines) as it attempts to not limit the scope to qualitative work. As I've written about elsewhere ([Kuby and Christ, 2020](#)), inquiry is not able to be planned or created in pre-set methods, thus I use the term 'qualitative inquiry' instead of 'qualitative research' which is laden with a history of methods, which in many cases have become formulaic.

I invite you to (re)read the opening quotes by Barad and St. Pierre. Go ahead, look back at the first page, read the quotes, let them wash over you, sit with them for a little while. Are you open to the aliveness of theory? The reconfiguring of the world that theory does? Are you willing to have some thought experiments? Can you forgo well-known methodologies for the possibility of an unknown? Can you lean into not knowing what to do next and next when doing inquiry?

In this chapter, I sketch a brief history of literacy research traditions and why I found myself not able to *not* think with post-inspired philosophies once I started reading and experiencing them. Woven throughout the chapter, I discuss my research partnership, since 2010, with early childhood/elementary teacher, Tara Gutshall Rucker. We conceptualized the idea of literacy desirings based on poststructural and posthumanist philosophies. I expand on the inquiries we found ourselves thinking and experimenting about and how it shifted our research practices as well as pedagogical practices. I discuss why PQI is needed to get our (literacy

community) minds (and bodies) out of the groove and how this has unfolded for me and other literacy researchers. I offer some resources that colleagues might find helpful related to post-philosophies and the doing of inquiry and end with an invitation to readers.

Historic traditions and a move toward post-philosophies

Briefly, I discuss a history of approaches to doing literacy research; however, I do so not to present a linear, chronological story nor to set up a binary of “historic” versus “new” ways of doing inquiry. Rather, I share these to situate the chapter and the many, multiple ways literacy research happens, as many of these traditions are still alive and active in how we do research today. Historically, in literacy education we’ve operated within positivist and phenomenological logics of empiricisms (see [St. Pierre, 2016c](#), for discussion on three empiricisms). Logical empiricism or positivist empiricism assumes measurement can be precise, objective, and seeks to measure, explain, predict and then control (intervene). This manifests in most quantitative and mixed methods studies and, to some extent, in some qualitative studies (e.g., some case studies). This type of empiricism typically focuses on epistemological projects (knowing, knowledge). Phenomenological empiricism describes most conventional humanist qualitative research with claims made on people’s “lived experience” or the word-for-word transcriptions of interviews and “letting the data speak for itself.” This empiricism manifests in most qualitative studies (e.g., ethnography, narrative inquiry, phenomenology, discourse analysis) and typically focuses on epistemological projects.

As a field we’ve focused on research inspired by structuralist theories which focus on language, phonemes, phonics, vocabulary and so forth (e.g., [Adams, 1990](#)), constructivist theories of emergent literacy (e.g., [Teale and Sulzby, 1986](#)), social constructivist theories of literacy as socially and culturally mediated activities (e.g., [Vygotsky, 1934/1962](#)), transactional language development theories (e.g., [Harste, Woodward, and Burke, 1984](#)), participatory apprenticeship inspired by neo-Vygotskian and cultural-historical activity theories (e.g., [Rogoff, 1995](#)), anthropological socialization theories ([Heath, 1982](#)), dialogic identity ([Holland et al., 1998](#)), critical literacy theories ([Lewison et al., 2015](#); [Vasquez, 2014](#)), sociopolitical and discourse acquisition theories ([Street, 2000](#); [Gee, 2001](#)), social semiotic and multimodality ([Halliday, 1975](#); [Kress, 1997](#)), and new technologies and material culture ([Marsh, 2006](#), [Wohlwend, 2009, 2011](#)). For more details on these, see [Crawford \(1995\)](#) and [Kuby et al. \(2019b\)](#) who each trace various paradigmatic, methodological, and theoretical histories of (early childhood) literacy research.

For each of these philosophically and theoretically inspired bodies of research, particular research practices are (un)thinkable or (im)possible depending on the assumptions on ontology, epistemology and axiology that in turn create methodological practices of data production and analysis, and thus paradigms for doing inquiry. For example, when drawing upon social semiotic and multimodality theories, particular ways of doing inquiry are possible, such as multimodal analysis. Particular types of data are collected or produced. Particular claims about a humanist subject interacting in a world of materials, are possible. Each of the theories above all have (at least) one common thread: they are all rooted in a Cartesian, humanist logic of the subject.

An example of a shift toward post-philosophies in literacy studies, comes from my book with co-researcher/teacher Tara Gutshall Rucker ([Kuby and Gutshall Rucker, 2016](#)). We spend several chapters unpacking how post-inspired inquiry looks different and demands different ways of thinking about the (human) subject and literacy, specifically we focus on sociocultural theories and New Literacy Studies perspectives. This is not to position them as binaries or in opposition to post-philosophies, but rather to consider what post-philosophies have to offer or what they make (im)possible and (un)thinkable for doing inquiry. It is an affirming reading of one theory with/through/in another or sometimes referred to as diffractive readings ([Murrin and Bozalek, 2019](#)). One example we begin the book with is an orange-paper-frog-puppet-Riley-fly. We think with the coming to be of the puppet in relation to the second graders, to Tara, to discourses on literacy, to artistic materials and tools, to the physical space of the classroom, and so forth. Thinking-with and becoming-with this literacy desiring example produced a space for us to consider the affectual ways literacies come to be, literally there was stickiness between people and non-humans (e.g., tape sticking to desks and fingers, paper frog tongue jetting out to person/fly’s arm). Materials matter, or said another way, how materials are in relationship with each other matter in literacies coming to be. We needed post-philosophies to help us think. To help us think of *how* and *why* literacies come to be. To help us consider literacies otherwise. To help us consider our relationality as pedagogists and the ethics and justice of our work as teachers/researchers.

Poststructural and posthumanist philosophies shocked our thoughts and forced us to rethink literacies. We introduced the concept literacy desiring(s) first in a *Journal of Early Childhood Literacy* article ([Kuby et al., 2015](#)) and then in our book. We conceptualized literacy desiring as:

...literacy processes (the becoming of artifacts such as books, movies, dramas, 3-D models, wall murals, puppets, and so forth) and to emphasize the fluid, sometimes unintentional, unbounded, and rhizomatic ways multimodal artifacts come into being through intra-actions with humans and nonhumans (i.e., time, space, materials, environment). Literacy desiring is oriented toward the present (ever-changing) needs, wishes, and demands of students-with-nonhumans, but also with possible users of literacy artifacts in mind.

[Kuby and Gutshall Rucker \(2016, p. 4\).](#)

Since then, this concept has morphed, grown, and challenged us as we continued to read post-philosophies and engage with the lively relations with/in Tara’s classrooms ([Gutshall Rucker and Kuby, 2020](#)). Our inquiry processes of literacy desiring coming to be

have also changed how we think of the doing of inquiry. Or said another way, we couldn't continue to think in a Cartesian logic of humanism and explore literacy desiring pedagogies *and* post-philosophy(ies) inspired research practices. Our doings (both pedagogically and methodologically), if inspired by post-philosophies, had to be experimental, a wild empiricism as Olsson (2009) writes about. Or as St. Pierre (2016c) states, a transcendental empiricism based on post-philosophies. Transcendental empiricism research employs post-philosophies and these philosophies have specific conceptualizations for the subject, knowledge (epistemology), reality (ontology), relationships and ethics (axiology), agency and power, and so forth. Thus, analytic, inquiry practices must be invented anew in each inquiry. Instead of asking *what* questions, research in these post-philosophies traditions seek *how* and *why* questions focusing on ontological phenomena. This research is experimental, creative, and unfolds in the moment of researching rather than pre-planned methods. Or as Stephanie Springgay discusses, permeable curiosity and curational planning of the not yet known (see webinar with Stephanie Springgay https://www.youtube.com/channel/UC4P_GUK6QV2Wp_OAWEpw87Q).

Thus, I've written about how post-philosophies changes how one thinks of research questions, literature reviews, data collection and production, analytic practices, relationships with 'participants' in a lively human and more-than-human world, and ways of (re)presenting and writing up of research (see Kuby, 2017a,b, 2019a,b). For too long, methodology (and perhaps pedagogy) has overlooked ethico-onto-epistemological discussions. Why? As St. Pierre (2016d) offers, perhaps "first, because we teach too much of the former [research methods] and not enough of the latter [philosophies and theories], and second, if we do teach onto-epistemology, we teach it separately from methodology", and I'd add separate from discussions on (literacy) pedagogy(ies) (p. 4). Simply put, "...where we might go is always enabled by where we've been" (St. Pierre, 2016d, p. 6). The aim is not to perpetuate binaries of methods versus theory (or even pedagogies) or to create hierarchies among them, but rather think (do) them together.

Why post qualitative inquiry is needed: releasing our minds (and bodies) from a groove

PQI is a label that some identify with and others, who engage with post-philosophies and inquiry, do not. The focus of this chapter is not to trace the histories of PQI and try to articulate what counts (or not) as PQI and/or who identifies with that label (or not). But rather, I hope to articulate why inquiries inspired by post-philosophies are needed and how the philosophical assumptions demand different, experimental ways of doing inquiry. St. Pierre (2016d), in advocating for untraining ourselves as educational researchers, writes:

Even formalized, pre-existing methodologies in which a systemic process guarantees the truth of the product cannot save us from the unimaginable to come. One could make this more complicated by presuming that the unimaginable is not necessarily exceptional but ordinary, that our everyday, normalized thoughts and practices produce "minds in a groove" (Whitehead, 1925/1967, p. 197) that prevent us from recognizing the exceptional that is always everywhere but outside the narrow groove in which we live and think and do (p. 7).

The exceptional is always, already everywhere in a lively world of humans and more-than-humans, a world in which some humans experience the world 'more fully' than others and others in (less than) inhuman ways (see scholarship by Mel Y. Chen, Karin Murris, Julietta Singh, Nathan Snaza, Sarah Truman, Alexander Weheliye). For example, if our minds are in a groove of what counts as literacies or defines literacies, we might not 'see' the literacies and processes of literacies coming-to-be in spaces and relationships that lie outside of our definition of literacies. For example, I think of Abigail Hackett's (2021) scholarship with very young children creating literacies with pinecones and flowerpots or in museums spaces. Some might argue these encounters with language, materiality, and aspects that *escape* language and representation aren't literacies. However, Hackett writes of the ways she acted like an ethnographer but thought with posthumanism. Inspired by post-philosophies, she situates literacies as mundane politics of the everyday.

A key article I use when teaching inquiry courses is one by St. Pierre (2000) where she outlines the philosophical assumptions or grids of intelligibility of poststructural feminism. As I've written about elsewhere,

I often assign this reading in research courses I teach, not because I think all students should align with this paradigm but, rather, because I want them to be able to map out a similar paper and/or concept map for the paradigm(s) they work in as scholars. In other words, I want them to be able to articulate the assumptions on language, discourse, the subject, agency, knowledge, truth, and so forth within the paradigm(s) they align with for their research so they can articulate what is possible or thinkable for the doing of inquiry. Said another way, these aspects of a paradigm impact how one thinks of research design, data production, how one works with participants, interviews, field notes, analytical tools, and representation of insights from the study (and are all of these even possible or thinkable for all paradigms!!)

Kuby (2021, pp. 56 and 57).

Thus, as literacy researchers it matters how we think concepts such as the subject, agency, knowledge, truth, power, resistance, freedom, discourse, language, and so forth as these all produce ways of doing inquiry. It matters for how we understand our history(ies) and past as a field, it matters for the present and how we do inquiry (and evaluate it) now, and it matters for the future, not

only for us as researchers in the often siloed academy, but also for what realities, relationships, and literacies come to be for the children, families, educators, and our planet.

For example, by examining a predominant perspective in literacy education – New Literacy Studies — we can see through an affirmative and diffractive reading, that particular philosophical perspectives make some inquiry practices thinking or possible and others don't. This doesn't mean we don't learn from both perspectives, we just learn something different(ly). This shift in literacy research toward inquiry inspired by post-philosophies (e.g., poststructural and posthuman) is needed for several reasons (see [Kuby, 2017a](#)). First, most paradigmatic and theoretical perspectives in literacy education focus on logocentric and anthropocentric inquiries, meaning the philosophical ways language and human is conceptualized follows a Descartes separation of mind/body and rests on assumptions that language can represent an experience. Second, thinking with poststructural and posthuman together is productive and generative to rethink the human in relation to literacies. This thinking-together-with-poststructural-and-posthuman is an affirmative process of reading one with/through the other (diffraction). Third, post-philosophies rest on the notion of ethico-onto-epistemologies and thus for literacy educators, when we think with them, our inquiry practices and pedagogies must consider doing (relationships, ethics), being (reality), and knowing (knowledge of literacies). Ethico-onto-epistemologies thus force or demand us to consider ethics/relationships/justice *with* consideration for realities and what is produced in the world *with* discussions on literacies, knowledge, and teaching/learning. Finally, the [Kuby \(2017a\)](#) article also discusses how the 'material turn' builds on the 'linguistic turn', but also begs us to think differently about language, discourse, materiality, subjectivity, and so forth in relation to inquiry practices. Thus, research inspired by post-philosophies should feel, look, and sound different. It should produce something different in the world, it should shock our thoughts ([Massumi, 2002](#)).

In another publication ([Kuby, 2017b](#)), I expand on these four tenets with a data-example of second graders, Elza and Raisa's making of a blue-paper-pipe cleaner-purse during Writers' Studio in Tara's classroom. I illustrate, with this example, how post-philosophies shifted how and what we think is (im)possible or (un)thinkable in regard to research questions, producing data, interviews and transcripts, and analysis and writing up of research. This publication, and others, invites scholars to consider: what is (the) social? In other words, we claim to do social science research, we claim to look at social interactions as qualitative inquirers, but what do post-philosophies demand or force us to think about the concept of social? How is social conceptualized and what does our conceptualization of social do to our inquiry practices? In two additional publications, we focus on two data examples from Tara's second grade classrooms to rethink social inspired by post-philosophies: a silent puppet show or puppeting ([Kuby, 2019a](#)) and the coming to be of a to-scale solar system wall mural ([Kuby and Crawford, 2018](#)). For example, in the silent puppet show, one might see the skit as a flop or not worthy of being considered a literacy and/or even 'successful' as an example to research. There wasn't much human talk, it was a quiet skit and appeared difficult for the human bodies in the audience to follow along. Constraints of chronological time, uncertainty of a storyline, and the materials (e.g., puppets, a stool, the set) all worked in relationship with the students performing the puppet show. The social phenomenon came to be because of relationships, in the moment, but also in relation to past/present/future entanglements of time. Social could no longer be thought from a Cartesian logics of human.

As I continued to read post-philosophies, my thinking on inquiry continued to become anew. For instance, in [Kuby \(2019b\)](#), I write a section on what PQI demands of researchers and focus on the following: an understanding of new empiricism, resisting binaries and the philosophical assumptions they rest upon, understanding non-representational logic and transcendental empiricism, rethinking subjectivity, and a focus on ethico-onto-epistemologies. In an introduction to an edited book on posthumanism and literacy education ([Kuby et al., 2019a](#)), we frame the book on how posthumanisms shift our constructions of child and childhood, shifts what counts as literacy, and requires that our focus as literacy researchers is on producing (what is produced, why, and how), not solely on meaning making and literacy artifacts (epistemology).

What post-philosophies have produced for literacy studies

For myself, and I suspect for others, this shift into post-philosophies happened through reading outside of literacy education. Specifically, in qualitative inquiry, Indigenous studies, women and gender studies, feminist theories, environmental sciences, and philosophy to name a few. In addition to 'scholarly' publications, reading novels, paying close attention to mundane or everyday interactions, media, and for me, the life of classrooms and schools. For being open to something to shock my thoughts, as [Massumi \(2002\)](#) writes, and for events that wrest me from my natural stupor as [Deleuze \(1968/1994\)](#) writes. And in this thinking-reading-with-the-world I find myself asking what does this matter for pedagogies? How does this relate to the teaching/learning of literacies? What might this reading have to offer literacy education? Or what questions or ways of thinking does this reading make possible, not only for pedagogies, but also for inquiry practices? Below is a sampling of some of the scholarship in the literacy education community that has stretched us to (re)consider ethico-onto-epistemologies, the ethics and justice of this work, and to be open to literacies (and inquiry practices) as otherwise.

As Tara and I have written about elsewhere ([Kuby, in press](#); [Kuby and Gutshall Rucker, 2020b](#)), our relationship began with readings on multimodality and pedagogical resources about writing workshop. However, as Tara shares, a quote by Gail [Boldt \(2009\)](#) wrested us from our natural stupor:

To continue work on the piece at the teacher's insistence would shift his [a child, Kyle] role. Instead of using the writing for his own purposes, Kyle would have to assume a position of compliance ... space for young children to use materials, social relations, and time in the classroom for anything other than predetermined academic outcomes—in other words, the time to play with ideas, materials, and one another—has largely disappeared in today's classroom (pp. 11 and 12).

In addition to this quote, there are also a few comments or questions from me about pedagogical interactions that stuck with Tara and opened up spaces for conversations (see [Kuby and Gutshall, 2020b](#); [Kuby, in press](#)). Comments and questions that might have otherwise gone unnoticed — what to me seemed like mundane everyday interactions and questions in a researching/teaching partnership. In our first year together, we began to wonder what would happen if we opened up writing workshop with an invitation to “go be a writer” with a range of artistic and digital tools. How would the matter (artistic and digital tools) literally matter in what could be(come). This inquiry was a catalyst for all our writing-thinking thereafter. Our partnership as inquirers began to focus on time, space, materials, permission and trust (see [Kuby and Gutshall Rucker, 2016](#)). Around this same time, I had read (over and over) a piece by [Leander and Rowe \(2006\)](#) drawing on Deleuze and Guattari's concept of a rhizome with literacy examples. From this, we began to read more and more post-philosophies (e.g., Deleuze and Guattari, Derrida, Barad, Braidotti, Haraway, Bennett, Wall Kimmerer). I also began to read publications and attend conference sessions on inquiry inspired by post-philosophies. Once I began reading these perspectives, I (or we) could not *not* think-with it. It became how I saw the world coming to be as well as literacies, pedagogies, and inquiry practices. It wasn't a 'lens' for me to put on or take off or even 'apply' to data for analysis, it was a way of being *and* knowing *and* doing with/in the world.

Our questions became ethico-onto-epistemological in nature, meaning, we weren't solely focusing on epistemological questions that often dominate (literacy) education research such as: What does a piece of writing mean? What does the child know about writing or reading? What literacy skills are not evident? And so forth. Instead we were asking ontological questions about how we come to know and the ethics and justice of these inquiries and pedagogical practices. For example, what does it do or produce for children, literacies, relationships, the school, the world when children are invited to be writers with a range of artistic and digital and linguistic tools? What are the ethics of these pedagogical moves, inspired by post-philosophies, in our day-to-day, often mundane interactions? What is the ethics and justice of the now or in this moment rather than justice that may or may not come in the future?

We are now wondering: What is writing? What are literacies? And we believe how we come to conceptualize writing and literacies makes the world. Or, said another way, how we think writing and literacies also makes identities and subjectivity and relationships in literacy classrooms (see [Kuby and Gutshall Rucker, 2020a](#)). How we conceptualize writing and literacies makes some things (un)thinkable and (im)possible. For example, in a piece sub-titled “The End of the Book and the Beginning of Writing” inspired by a chapter by Derrida in his book *Of Grammatology* (1974/2016), we redefine writing and reimagine writers ([Kuby and Fontanella-Nothom, 2018](#)). We illuminate how second graders deconstructed and defer the meaning of writing and what counts as writing, with the pedagogical spaces Tara provided, relationships among humans, and other bodies (paper, yarn, tape, googly eyes, etc.). As we wrote:

[Caputo \(1997\)](#) stated, “to desire the impossible is to strain against the constraints of the foreseeable and possible, to open the horizon of possibility to what it cannot foresee or foretell” (pp. 133–134). Tara, in order to remain open to new possibilities, had to allow herself to trust that there was a future she was unable to predict. A future unforeseen and unanticipated but yet welcomed and embraced and unfolding in the present ... *the impossible is always and already the possible*. We invite you to consider how the ‘end of the book and the beginning of writing’ or the end of how we've always thought about writing might produce aporias, which are already possible for (re)imagining writing.

[Kuby and Fontanella-Nothom \(2018, p. 324, emphasis in original\)](#).

Being open to have Derrida's words wash over us, so to speak, to not rush to understanding, but rather to see what they produced for us, our thinking, and literacies was our aim. Not having a single research question or focus ahead of time, but rather, seeing what might unfold when we think with Derrida and literacies from Tara's classroom.

Another example comes from a handbook chapter where Tara and I think deeply with one article by Karen [Barad \(2003\)](#) and a video that came to be among second graders with an iPad. The handbook chapter, “Posthuman Theory as a Tool to Explore Literacy Desirings: Sara-Taylor-iPad-Book Becoming in Writers' Studio” ([Kuby and Gutshall Rucker, 2020c](#)) was a theoretical and philosophical playground for us to imagine how concepts like intra-action, entanglement, material-discursive, and agential cuts, defined by Barad, produce new ways of thinking about literacies. It forced us to consider matter (re)configuring, unpredictable relationships (among human and nonhuman bodies), bodily apparatuses and lively agency, and becoming (tripod, video) together in Writers' Studio. For us, we needed philosophical concepts about a lively, more-than-human world to help us understand *how* and *why* (not solely *what*) literacies came to be in the Sara-Taylor-iPad-book example we focus on in the chapter.

In another handbook chapter ([Kuby, 2019b](#)), I share inventive and experimental inquiry practices that I've engaged with rooted in post-philosophies to think-with animal research creations and nonfiction writing made by second graders in Tara's classroom. The chapter aims to reimagine multimodal research inspired by post qualitative inquiry practices. I outline four inquiry practices and shared examples from the animal research creation projects:

- Thinking with theory inspired by Alecia Jackson and Lisa Mazzei's writing
- To think is to experiment, a statement from Deleuze and Guattari
- Creating concepts inspired by Deleuze and Guattari's notion of philosophical concepts
- Diffracting an idea based in quantum physics and discussed by Karen Barad among others

These four ways of thinking/inquiring aren't pre-set or even known in advance of doing them, they are tools that open up spaces for thinking otherwise and doing inquiry otherwise.

Again, for me, the ethics and justice, at the core of post-philosophies is paramount for literacy educators to consider. How subjects are thought or conceptualized and how ethics and justice are conceptualized matter in *how we come to be* in the world (identities, relationships, subjectivity, and literacies) and what is possible for our scholarship to *do* in the world. In a co-authored piece (Zapata et al., 2018), we put to work several posthumanist concepts with three data encounters. We illuminate writing as intra-activity; as trans-corporeal, porous, and lively; and as translingual assemblages. We invite readers to think about literacies as the not-yet-known. We write,

Just as critical theories have worked toward an unfreezing of deficit monoliths that often subtract, and colonize and terrorize, posthuman theories work toward a more just world by exploring what phenomena—such as deficit monoliths—produce and the very real consequences they have on the worlds they create, such as the worlds of young writers.

Zapata et al. (2018, p. 497).

Thus, it is exciting to see more scholars thinking-with post-philosophies and matters of justice. Some scholars are thinking-with post philosophies in relation to translanguaging and translingual picturebook making (Zapata and Kuby, 2021); social class (Thiel and Jones, 2017); race (Franklin-Phipps and Rath, 2019; Thiel and Dernikos, 2020); language and representation (Hackett et al., 2020a); and lesbian, gay, bisexual, transgender, and queer communities (Wargo, 2019). There are edited collections in journals and books that pull together international scholars to think-with a variety of post-philosophies and the doing of inquiry for literacies and language and intentionally explore intersections with multimodal and critical theories (Hackett et al., 2020b; Kuby and Rowsell, 2017; Kuby et al., 2019a). These scholars are trying to (re)imagine language and literacies (education) and inquiry practices.

For those new and inspired to learn more about PQI, there are some resources that one might find helpful in addition to these readings. A webinar series titled, "Post Philosophies and the Doing of Inquiry", has fourteen webinars with international scholars doing inquiry with a range of post-philosophies and the recorded sessions are available on YouTube: https://www.youtube.com/channel/UC4P_GUK6QV2Wp_OAWEpw87Q. A new book series with Routledge titled, "Postqualitative, New Materialist and Critical Posthumanist Research" explores the doing of inquiry with these philosophical traditions. Two videos I also find helpful in thinking of post-philosophies, specifically posthumanism, are by Cary Wolfe (2012) and Michael Shirzadian (2018). Watch these and ask yourself questions such as:

- What does this video produce for you and your thinking about literacy?
- What are the desires and imperatives of humanism in relation to literacy? Should we question these?
- What might be the theories and philosophical perspectives of these humanist literacy projects? Are they self-defeating? Problematic?
- Why might we need a post-philosophical perspective in literacy education? What could it produce? Make possible?

In addition to these resources, there are many new books on post-philosophies and the doing of inquiry and resources such as a posthuman glossary (Braidotti and Hlavajova, 2018; Murris et al., 2022). Many post-philosophers have recorded lectures available on the internet, which I find helpful to consider alongside their writings.

Invitation to think and do inquiry otherwise

St. Pierre (2016d) writes, note my emphases added in brackets:

Methodologies seem to stand alone, separate from the interpretive [and I'd add, positivist] approaches that produce them. An educational [literacy] researcher can now "do" research by following a recipe without having to "think" much at all ... Does thought need a method to steer it? Does inquiry need a method to control it? What might educational [literacy] research become if it were free of the hegemonic pretensions of methods, if it were *methodology-free*? ... I like to imagine educational [literacy] research-to-come as difference instead of repetition when those who inquire do not know what to do next but trust that something new might come out of "experimentation in contact with the real."

Deleuze and Guattari (1980/1987, p. 12) (pp. 9 and 10, emphasis in original).

Trust that something new might come out of experimentation in contact with the real. I hope this chapter serves as an invitational space for educators, specifically in literacy education, to be open to other possibilities for the doing of inquiry. Post-philosophies demand us to (re)think what is (im)possible for doing inquiry. As Braidotti (2018) writes, "The driving

force for knowledge production is therefore not the quest for knowledge for disciplinary purity, or the inspirational force of radical dissent, but rather the modes of relations these discourses are able and willing to open up" (p. 44). What are we (you) willing to be a part of opening up? As [St. Pierre \(2016a\)](#) cautions, this turn to post-inspired inquiry with attention to ontology, is not an "add ontology and stir" approach. Rather, in regard to research practices, we must question dogmatic images of thought (inspired by Deleuze) or our minds in the groove (inspired by Whitehead). People made up what has become normalized or taken for granted ways of doing research. We can (re)think and question them *and* invent new ways of inquiring.

We need more research that operates explicitly from post-philosophies which focus not only on epistemology (literacy knowledge) but also ontology (what is produced and for whom) and axiology (how it is produced, in what relationships). We mustn't feel afraid or threatened by new ways of inquiring about/with literacies. If we continue to do research in the same ways—to repeat, repeat, repeat—our understandings about the world and our doing and being in the world will continue to produce the same. Replication and circularities in our research continue to reiterate the same ways of conceptualizing literacies, teaching literacies, and researching literacies. This matters for bodies—students, teachers, non-living bodies—and the lively world of discourses, policies, languages, animals, plants and so forth. It matters for how our world comes to be and what realities are produced. Who we are does not pre-exist our relationships with each other. We all come into being through relational fields or subjectivity (see [Kuby and Gutshall Rucker, 2020a](#)). Many trans/interdisciplinary scholars are helping us consider how humanist theories of the essentialized subject and identity(ies) (i.e., theories of intersectionality) might need to be thought-with post-philosophies if we aim to create a more just and ethical world (e.g., Jasbir Puar, Jennifer Nash, Mel Y. Chen, Karin Murris, Julietta Singh, Nathan Snaza, Sarah Truman, Alexander Weheliye). It would serve the literacy education community well to read broadly from trans/interdisciplinary communities of scholars and put the ideas to work in literacy education.

How we define something, the labels we use matter. How we define literacy is an ontological project and it matters in producing people, the world, pedagogies, assessments, relationships, literacies, and so forth. Thus, a matter of ethics and justice. We have to consider how bodies engaging in post-inspired philosophy inquiry will produce research that doesn't look like normalized, conventional humanist research that we are used to. We have to consider that how ethics and justice is thought and discussed inspired by post-philosophies might not look nor sound like traditional critical theories that we've become so familiar with. We have to consider what changes might need to happen with promotion and tenure processes, article reviews for journal, funding mechanisms for research, proposal reviews for conferences, and advising and teaching of students. As I've written about with others ([Ward et al., 2018](#)), colleagues are quick to judge and apply conventional humanist research standards on post-inspired philosophy inquiries, before pausing to consider *why* and *how* it might look and sound different. I've found an article on *humanities-oriented educational research* helpful in thinking differently about research ([AERA, 2009](#)). This article offers rationales for why *humanities-oriented educational research* is needed and ways to consider evaluating it. We need to be more generous to the otherwise and not yet known, rather than continue to enact normalized ways of doing inquiry and assumptions from the paradigm(s) one is most familiar with.

In the broader educational community, [Snaza and colleagues \(2014\)](#), among others, have begun to wrestle with the criticalness and ethics of post-philosophies inspired work in curriculum studies:

We are forwarding posthumanism not as a new "discourse" per se, but rather we are forwarding posthumanism as a way of recognizing that a wide variety of seemingly disparate critical approaches (feminism, anticolonial and antiracist thought, technology studies, ecology, etc.) have a common ground in directly challenging the ways humanism has restricted politics and education ... We problematize all human/humanist-centric theories because previous critiques of humanism's violence have functioned as what [Sedgwick \(1990, p. 85\)](#) calls "minoritizing" discourses—discourses that matter to some people (women, the formerly colonized, etc.) and can be easily dismissed or ignored by those with the privilege of not needing, wanting, or choosing to care. We believe posthumanism pushes intersectionality to the point where no one—no matter their field, interest, or position of power—can afford to ignore these critiques (p. 41).

Thus, for me, post-philosophies don't allow for Othering or binaries (me vs. them), or simply critique based in critical theories. But rather, they demand I always think about my power, position, and privilege – which comes into being with/in each relationship and encounter – in all my relationalities, that I am already, always a part of. I have a response-ability that I can't ignore ([Barad, 2007; Haraway, 2016](#)). As [Snaza and colleagues \(2014\)](#) write:

Consciously or not, we educators and educational researchers are used to looking at schools as places where humans dwell together to learn what it means to be human and to accumulate the kinds of skills and habits required to participate in human societies as adults. This occurs in spite of the fact that schools are connected with the nonhuman world in so many explicit and implicit ways ... we are not the center of the universe. Indeed, we should not be the center of conversation (pp. 39 and 40).

What is the future, that is yet to come, of literacy education? A future that is already entangled with the present and past histories and many bodies. Join in creating the not-yet-known for literacies education.

Acknowledgments

This publication would not be possible without the collaborative researching-teaching-thinking-writing partnerships with co-authors of my publications. Specifically, with Tara Gutshall Rucker, whose artfully, skillful teaching continues to inspire me. I am grateful for her continued commitment to think-with me.

Introduction: humans in the city

We arrived at Mariachi Plaza early on a Saturday morning to set up. It was already bright out, a warm, blue, cloudless sky covering the historic plaza. Like Mexico City’s Plaza Garibaldi, Mariachi Plaza in Los Angeles is the city’s symbolic home to mariachi music, with mariachi musicians lingering in the plaza every day, waiting and hoping to be hired on the spot to perform, heritage culture meets day laborer. Located in the historic immigrant and now almost entirely Latinx neighborhood of Boyle Heights, Mariachi Plaza has at its center a kiosk (or gazebo) donated to the city by the Mexican state of Jalisco, an entrance to the LA subway, and a stage for performers. Around its periphery exist a number of family-run shops that are important to the community’s culture and livelihood. We put out tables, signage, canopy tents to provide some relief from the sun, and arranged an array of maps, art supplies, and photo booth props for our project. Over on the stage, we set up a station where artists would work with large cardboard pieces to make life-size human silhouettes.

We were setting up for an art project that we called “Boyle Heights en Movimiento.” I was the professor in a humanities studio, working with a team of students from the course, the non-profit organization People for Mobility Justice (formerly known as Multicultural Communities for Mobility) who advocates for safe, alternative transportation access in underserved communities of color in LA (2022), and the historic Latinx and Chicana art organization Self Help Graphics & Art which was based in Boyle Heights (2022). People for Mobility Justice had worked with some other community organizations to organize a group bike ride, its starting time and place coinciding with our project, and cyclists, families with children, and curious passers-by began to walk up to our booths. Some members of the student team worked with people to collect cognitive cartography, mapping out with marker and paper where cyclists were safe or unsafe, where they understood their place in the city, and what they wanted their neighborhood to become. Others conducted surveys, and others rewarded those who were willing to engage with us with a custom Polaroid portrait. We were also collecting our own photographs of bodies and bikes for our art project. Together, we were trying to imagine how we could harness the power of art and the critical capacities of the humanities to pursue advocacy for cyclists in Los Angeles.

As you read this sentence, even with all of the context of the Latinx neighborhood of Boyle Heights, the phrase, “advocacy for cyclists in Los Angeles,” comes with a pre-cooked imaginary. Typically, we can picture mostly white upper-middle class cyclists who perhaps bike to work, but are especially enthusiastic about the healthy lifestyle of cycling as a pleasurable activity. To extend the LA stereotype, let’s add in green juice, lycra shorts, acai bowls, sunshine, and other features of the health-centered lifestyle. Advocacy involves using the connections of this plugged-in segment of the population to pressure local governments to add bike lanes, and often these bike lanes lead to a large urban-scale recreational path where cyclists can enjoy their biking totally free from cars and with the benefit of local flora. While there is much to be lauded within this imaginary, it is problematic insofar as it excludes a large portion of the bike riding population. These excluded communities are typically lower income communities of color who bike not for pleasure but out of necessity, cycling to work because other means of transit are too time intensive, physically inaccessible, or expensive. These cyclists don’t see bike lane advocacy as something that happens for them — helmets and bike shorts are a luxury, while dangerous roads are a reality. These are the thorny issues that People for Mobility Justice grapples with on a daily basis, and the ones that we sought to engage with our project.

Fig. 1 Design mockup for a “ghost silhouette,” created by student team of Angélica Becerra, Peter Chesney, Paul Kurek, Lucy Seena K Lin, Jeannette Mundy, and Teo Wickland. Source: the author.

Back on that Mariachi Plaza stage, an artist from Self Help Graphics & Art took one of the photographs we were taking and re-drew it as a silhouette, projecting it to life size on a piece of cardboard and then cutting it out, fashioning a perpendicular piece as a base so that this ghost of a cyclist could stand on their own. This was the first of what would become a community of ghost silhouettes, distributed throughout Boyle Heights and Los Angeles in locations that were designated as high-risk to the cyclist community represented by People for Mobility Justice (see [Fig. 1](#)). These ghosts acted to both slow down drivers to speeds that were not lethal, and hopefully spark some tiny bit of reflection about this invisible community of bike commuters in Los Angeles.

The idea emerged from a collaborative effort where we discussed an artist that had inspired us all: Jay Lyn Gomez, the young, Mexican American artist who was taking the world by storm with her striking reimaginings of well-known works of art, advertisements, and even architectural spaces (for more information, see [Charlie James Gallery, 2022](#)). She forced spectators to recognize the people that were behind the work of art, the ones made invisible, by inserting them into our field of vision. For example, in perhaps her most well-known piece, titled *No Splash* (2014), she repainted David Hockney’s famous *A Bigger Splash* (1967), but instead of seeing the splash of a member of the leisure class jumping into a pool, we see a brown body at work, cleaning the very same pool. In another series of works titled *Cut-Outs* (2015), Gomez produced life-size cutouts of gardeners and other day laborers, inserting them into the manicured lawns of wealthy Angelenos and other locations where we might forget about these “essential workers” the moment they are outside of our field of vision. These cutouts are what inspired our own project, using cheap and easily available materials and our own creative capacities to try and spark a new consciousness around us.

Developing urban humanities *in situ*

Backing up a bit, you might be asking, how is this from a class in the humanities? What, exactly, are you even teaching? And what is a “humanities studio”? The students working together were completing the capstone of a year-long curriculum where they had closely read, analyzed, and debated texts that spanned disparate disciplines and topics but were united by being situated within the geography of the US-Mexico borderlands, reaching from Mexico City, through Tijuana, up to Los Angeles. To teach across such a wide swath of territory, we had a faculty teaching team from architecture, urban planning, and the humanities. The students, themselves, came from a range of fields, from the creative and applied fields of architecture, design, and art; from the socially and spatially oriented fields of urban studies, including urban planning, geography, and public policy; from interdisciplinary area fields such as Chicanx studies; and from the range of humanities fields, including Spanish language and literature, English, history, and philosophy. After engaging deeply with texts, films, histories, and geographies intellectually, from the classroom, we undertook site-specific and engaged field learning through trips from our home base at UCLA to Tijuana and Mexico City. All of this was financially and intellectually supported by the Mellon Foundation through its multi-year and multi-institution project called Architecture, Urbanism, and the Humanities which, to date, has distributed over \$36 m across 31 different grants ([Mellon Foundation, 2022](#)). This whirlwind of activity and resources was beyond extraordinary for a public university, but it also raised a number of questions for all of us as participants in this journey — questions that came to define the very thing that we called urban humanities (for a more in-depth exploration of urban humanities and numerous international example projects, see [Cuff et al., 2020](#)).

First, what are the humanities? While this seemingly simple question demands an answer of far more depth than I will provide here, I will at least point to a few observations relevant to the formation of urban humanities. One simple way to answer the question is by way of contrast: while both the humanities and the social sciences are categories of academic and applied practice which focus on people, where the social sciences focuses on generalizable patterns within populations, the humanities turns its gaze upon the fully humanized and embodied person. The social scientist tends toward positivist, quantitative, and macro-level approaches, while the humanist tends toward critical, interpretive, and micro-level approaches (see, for example, [Kagan, 2009](#)). Thus, the social sciences tend to be better suited to engage with some questions (e.g., “what is the economic impact of this policy on that region?”) and the humanities with others (e.g., “how does the language of this policy give insight into its authors and their intentions?”). The original question — what are the humanities? — remains, however, impossible to answer in any kind of complete and

comprehensive way, especially for a single person — and, indeed, this is precisely the conundrum that led to urban humanities. As the world becomes increasingly vast, as everything around us speeds up, it becomes increasingly difficult for any one person to hold all of the knowledge and expertise necessary to understand nearly anything in its entirety. This is true for categories as broad as the social sciences or the humanities, and it is true for the condition that we call “urban.”

The cultural object that we call “the city” could be described as a “hyperobject,” to use the philosopher Timothy Morton’s term (Morton, 2013). These are things that are so vast across spatial and temporal dimensions that our ability to see and touch them becomes disconnected from our mental capacity of understanding them in abstract terms. We can sit down on a park bench and feel as though we are “in the city” — but does that provide the necessary expertise for grasping the ubiquitous and global condition of the urban? Hyperobjects demand scores of people across multiple disciplines, working within and outside of academia, to come to any remote understanding of their nature. It’s a kind of approaching infinity: we are on a journey toward enlightenment, even if we never quite get there, nor expect to. Morton uses the term to describe environmental issues like climate change and, indeed, environmental humanities has emerged as a new scholarly practice to grapple with such a hyperobject (see, for example, Emmett and Nye, 2017; Heise et al., 2017). Other experimental humanities have similarly emerged: medical humanities, digital humanities, and so on. These cross-cutting fields demand new collaborative allegiances across fields, and with such interaction comes new languages and literacies necessary for communication, documentation, analysis, interpretation, and understanding. Urban humanities began in situ as a group of collaborators just trying to wrap their heads around the urban, and a handful of provisional values and practices emerged as we collectively struggled to move forward through darkness, engaging with a few additional questions beyond this.

Life in the “undercommons”

What of our privileged position within the university with funding from a private foundation, no less? Philanthropic giving, for all its good intentions and occasional ability to move faster or more experimentally than public funds, is noted for how it also acts as a means for the ultra-wealthy to undemocratically influence society and avoid paying taxes (see, for example, Reich, 2016). My urban humanities colleagues Jonathan Banfill, Todd Presner, and Maite Zubiaurre developed the ethic of the “porous university” as one response to this conundrum, emphasizing the need for schools to organize around “permeability, openness, interdisciplinarity, collaboration, and community engagement” (2016, p. 122). One can extend this ethos to private foundations, entities which are similarly situated to universities as non-profit, aspirational, yet powerful and often problematic. The philosopher-poets Fred Moten and Stefano Harney have written of the “undercommons,” an organizing principle that goes further than porosity, suggesting that for all the frenetic professional activity on the surface of the university, the real work happens under false pretenses, underground, in the fugitive undercommons. This teaching, scholarship, and collective life that happens off the books is both the real public good offered by the university and constitutes theft from the university (Moten and Harney, 2013). In other words, one ethical approach toward grant-funded academic work, as scholars and double agents, is to take as many of the resources in the university and from the foundation (Mellon Foundation included) and direct them toward channels of mutual aid, sending them into communities where there is the most need. This aspiration was never perfectly achieved, but guided our stance toward so-called “community-based learning and research” where we always asked if our partners were getting more out of our engagement than we were, trying in some small way to reverse the all-too-common extractive community partnerships that add to a glowing university marketing campaign, yet leave partners in the lurch at the moment that the university got what it needed.

Another thorny question: what of the problematic history of travel learning and research from the university, infamously “parachuting in” as colonizing experts who, once again, extract and exit? The UCLA urban humanities program emphasized the pressing nature of globalized urbanism and, as such, demanded collaborations and partnerships that spanned the Pacific Ocean — yet calendars and budgets only allowed for relatively short trips for faculty and students to our partners’ locales in Shanghai, Tokyo, and Mexico City (Cuff et al., 2020). Grappling with this question took several years of trial and error and was fundamentally intertwined with the nature of collaboration and partnership with community organizations under the rubric of the undercommons. One partial strategy was to spend as much time as possible “doing our homework”: studying up on the history and culture of the place that we were engaging. What was once a week of travel prep turned into a quarter-long seminar delving into historical readings and literature in translation, and this turned into two quarters of preparation before we were ever to even set foot in the place. What we learned was this: more preparation is better, but no amount is ever enough. This reality came home to roost most clearly when we undertook projects in our own backyard of Los Angeles: one astute student asked, well, why do we assume that we know LA any better than any of these other places just because we live here? Indeed, the vast, unknowable nature of the city ensured that a neighborhood just across town where we had hardly set foot was as foreign a land, filled with its own language, history, and culture, that we had no ownership over and little right to barge in, as a place on the other side of an ocean.

The organizing principle of the undercommons is, in part, an answer to this question. Inverting the “parachute” model of going into a place as an expert, extracting all the data and PR that one can out of the engagement and then heading back home to enjoy the benefits, we instead went as allies and co-conspirators with our collaborative partners, offering whatever resources we had (money, labor, information) and learning what we could about ourselves and our own struggles at home. Another key finding was the importance of duration, both for building the trust and shared language necessary for establishing meaningful collaborative partnerships, and also for the time necessary to complete impactful projects. In other words, our destination ceased to be our “site” of

intervention and instead more like service-training ground, and we returned back to our home as the real site of intervention where we could embark on projects without artificial limits to the length of time that we could commit to them. The format, over the course of a three-quarter academic year, included an introductory seminar on the “intimacies” between Los Angeles and Mexico City, a partnership-building “design seminar” with organizations on the ground in Mexico City concluding with a 10-day field practicum, and a culminating “humanities studio” where all of this learning was used as a catalyst for on-the-ground projects in Los Angeles in partnership with local organizations (see Cuff et al., 2020). Indeed, one such culminating project was the art and mobility collaboration described above. While our on-the-ground project involved issues and organizations in Los Angeles, it came out of learning from and deep engagement with texts, collaborations, and experiences in Mexico City, especially including innovative work on street safety. This inversion bears some relationship to recent ideas around decolonizing the university, foregoing the hegemonic unidirectional flow of “legitimated” knowledge from the university outward and, instead, opening up the possibility of transformation and Robinhood-like theft (see, for example, Mbembe, 2016).

The banking versus dialogic models of education

This inverted model of travel learning and research also forces us to reconsider conventional power relationships within teaching and learning. Of critical importance is educator Paulo Freire’s classic text *Pedagogy of the Oppressed* where he describes the conventional “banking model” of education — and, in turn, society — wherein the teacher, or other authority figure, merely “deposits” knowledge into the brains of students without concern for their agency, knowledge, or humanity and ultimately reproduces these oppressive power structures (Freire, 1970). Instead, he proposes a bidirectional or “dialogical” model of education wherein roles of teacher and student are dynamic and in flux, where equality brings liberation and freedom. The dramatist Augusto Boal created “theater of the oppressed” based on these principals, creating a model of performance that destabilized the roles of performer and audience in favor of a dialogical and recursive process of exploration which could yield mental and ultimately social breakthroughs for problems of injustice (Boal, 1985). And the philosopher Jacques Rancière describes the similarly disruptive notion of “intellectual emancipation” through analysis of the story of educator Joseph Jacotot who taught students through linguistic differences (Rancière, 1991). For Rancière, topical expertise is less important for a teacher than an abiding belief in the inherent intelligence and capability of human beings and the ability to create an emancipatory space of exploration, discovery, and learning. For all three of these thinkers, processes of learning mirror societal power structures: to learn based on the “banking model” whether it is in the classroom, in the theater, or in the workplace is to be told what to know and then to reproduce that process in others. Liberation and emancipation and “true learning” come through self-actualization as an agent with free will and the willingness to dialogically engage with equal peers, producing knowledge that is not dependent on social reproduction but, instead, new possibility.

These ideas are, of course, an ideal to strive toward, and never quite achieved, but they formed the basis for urban humanities work which blended practices of research, learning, and action, and positions of partner, teacher, and student. Sustaining these fuzzy definitions opened up possibility for unexpected learning, transformation, and collaboration. Design theorist Gerhard Fischer coined the term “symmetry of ignorance” for the social arrangement necessary as a precursor for equitable collaboration wherein no single actor can dominate power relations among the group (Fischer, 2000). Like Rancière’s “ignorant schoolmaster,” our shared humility and openness to each others’ contributions allowed for the formation of meaningful partnerships within our group and with organizations beyond it.

The humanities studio

All of this leads to the actual space of learning, a space that was critical to construct as the ground where dialogical and applied work could take place: the studio. The historic origins of the studio are hardly an equitable utopia: with origins in applied master-apprentice training, they are defined by “the banking model.” Nevertheless, philosopher Donald Schön sited his exploration of learning for what he called “reflective practice” within the architecture studio (Schön, 1987). The “reflective practitioner” is essentially an individual version of the liberated subject described by Freire and others, one who takes action in the world and can recursively examine one’s outcomes, learn, and then take new actions. The educational process of the architecture studio, however, demonstrates a model for collective liberation through dialogical peer learning combined with exploratory reflective practice. This studio-based learning departs from the power relationships historically embedded into it, in favor of open-ended, collaborative, and unexpected outcomes. Rather than a set of fixed topics that a student must learn, as is common in the lecture format class, or a fixed reading list that is to be discussed, as in the seminar, the studio instead poses a question or problem to solve. While the architecture studio begins with an architectural question — such as “how might you design a library for this irregular lot?” — the humanities studio begins with a humanistic question. How might the problematics of identity and representation be resolved within the film industry? How do we translate ancient texts into a format accessible to social media users? Or: how can artistic practices be repurposed to address a culturally specific urban mobility problem? Participants in the studio work collaboratively in an open-ended structure, taking initiative to learn whatever knowledge is needed on-the-fly, teaching each other as they work toward resolving a “wicked problem” (Rittel and Webber, 1973). This is the urban humanities that emerged “in situ,” built out of the questions that arose as we struggled to learn, work, and be together, striving toward an answer to a question.

Urbanism as collective life

The subject area focus of urban humanities is, ostensibly, “the urban.” But what is the urban? Beyond its condition as a hyperobject, there are a few additional qualities that are worth noting to better understand the literacies, practices, and pedagogies that come out of urban humanities. One starting gambit to this puzzle is to put forth the troubling yet illuminating claim posited by sociologist Henri Lefebvre in 1970: that *everything* is urban (Lefebvre, 1970). Lefebvre was not suggesting that every last person on the planet lived within city boundaries, nor that every object imaginable was actually a city in disguise. Rather, he was defining “the urban” as a condition of contemporary life under late capitalism, that the communicative, financial, and material flows around the globe had become so pervasive that we all, more or less, had access to urban life regardless of location. Even the rural village is filled with people who know what is happening in Washington, D.C. up to the very second through their smartphones, who can participate in a global cultural phenomenon of one dance or another on TikTok, is beholden to the same financial institutions as a co-op owner in New York city, with debt instruments held by thousands of investors around the world. We are all urban now.

This shift of the condition of urbanism away from a strictly material condition of dense living within a city’s core toward the inescapable conditions of contemporary life comes commensurate with a shift of urban studies away from, say, the study of high-rise building infrastructure (not to diminish this topic’s importance for particular questions), toward the sociotechnical and cultural manifestations of collective life under globalized and racialized capitalism. For this reason, contributing new approaches for urban studies to engage what scholar Lisa Lowe has referred to as “intimacies,” the transnational and recursive flows of culture and history, is increasingly urgent (Lowe, 2015). By focusing on these intimacies rather than more dated forms of urban studies which looked at cities in isolation, or in comparison to one another, you are able to engage with the urban condition without erasing cultural difference or, worse, reducing it to a false linear progression from places that are “more developed” or “less globalized,” to say nothing of the opposite extreme of situating urban phenomena as exotic manifestations of a “foreign” culture. Focusing on intimacies demonstrates the emptiness of terms such as “natural” or “authentic,” forcing us to reconcile our collective and interconnected dependencies and obligations with individuals on the other side of the globe. It reminds us that, if everything is urban, then to study the urban is to study everything, demanding humility and collaboration across discipline and difference.

It is no coincidence that urban humanities emerged out of the university, a place meant to capture the universal “whole”; there is something inextricable about the connection between the lofty ideals of academia and the “infinite” nature of the city, to use writer Rebecca Solnit’s term (Solnit, 2010). But now, as our work has demonstrated, the university has not turned out to be so universal, after all, and new connections must be built beyond academia, with and into the urban itself. Similarly, drawing from the theories that informed our pedagogical approach, one of Rancière’s key axioms from *The Ignorant Schoolmaster* is the idea that “everything is in everything” (Rancière, 1991). This paradoxical axiom points toward the intimacies that one can trace from anything in our interconnected and interdependent world: that to study the ring on the finger of a corrupt mayor, for example, is to quid pro quo study housing policies at the same time that one studies the international trade of blood diamonds. That urban humanities, in studying the urban, can focus upon the material histories and cultures of nearly any person, place, or thing, and spiral outward to build connections to a global web of other things, ultimately discovering new information about the realities of our contemporary conditions of collective life.

Since the urban humanities is situated within the humanities, it foregrounds a few elements that have often been overlooked through more social scientific approaches to urban study that have privileged abstraction, generalization, and quantification. One element is historical and interpretive: foregrounding the histories and cultures embedded in place highlight the importance of narrative, of the stories that come from places but also make places. These stories take the form of literal narratives, but also forms of shared language, symbols, and practices which can be interpreted and translated in dramatically different ways depending on who is participating, necessitating new literacies for this form of urban study. Local languages are, of course, incredibly important, but so are all the cultural and symbolic meanings that go beyond language, from foodways to rituals of daily life. Related to this is embodiment: the impact of positionality and the material conditions of the individual often go overlooked in the birds-eye view of quantification. The humanities force us to focus upon our human condition, dependent on one another and beholden to all of the possibilities and limitations that come with our bodies, from physical needs to mental biases, and beyond. And to extend our embodiment down this path one step further, it is especially important to recognize that interdependence: a single person does not make a society, a culture, or a city. Rather, to study the urban is to study our collectivity, to emphasize all of the ways that we help and harm one another, all of the ways that we share culture or misinterpret one another, how we are more interdependent on one another around the globe than ever before in human history. This fundamental reality is a key topic that urban humanities can uniquely mine, and one that is increasingly urgent.

Values of urban humanities: spatial justice and the practical future

To study our interdependence within the contemporary conditions of collective life is to also reflect on the values which drive such study. Academic work is often touted as purely objective and value-neutral, though any humanist will gladly dispel you of this notion: our work, regardless of field, is laden with our own values and biases, and the only way to deal with them is to be aware and intentional about them (see, for example, Haskell, 2000). To this end, two values surfaced in our work and became guiding principles to which we always returned. The first is the idea of *spatial justice*, a particular formation of justice which is particularly

attuned to the spatial orientation of urban studies. The second is the idea of *the practical future*, a critique in some ways of the academic approach which focuses on present and past without full engagement with the future, a future that we, intentionally or not, bring into being through our work.

Spatial justice

Spatial justice, especially as it connects to scholarly and pedagogy, was perhaps best described by geographer Ed Soja in his book *Seeking Spatial Justice* (Soja, 2010). In it, he applies the critiques and theories that came with the “spatial turn” of the 1970s–90s to our understanding of justice, arguing for the idea that justices and injustices can be spatially constructed, distributed, and resolved. Issues of spatial justice can play out at multiple scales. Extending his colleague David Harvey’s scholarship on the “right to the city” (2008; see also, Lefebvre, 1968), Soja notes that the drawing of boundaries for political representation can mean that some are better represented than other, which translates to differential access to power, which then turns into spatially distributed injustices such as worse pollution within an impoverished community that cannot fight the construction of a waste treatment plant, for example. But they can also operate on regional, national, and global scales: even now as I write this, there is a spatial injustice which is playing out globally where the distribution of COVID-19 vaccines has largely centered in the Global North, while almost entirely bypassing the continent of Africa. Beyond identifying spatial injustices, Soja also describes processes by which the fight for justice can also play out spatially. In one example, he reflects on the spatiality of the Los Angeles Bus Riders Union, which was a coalition of activists who fought for investment in LA’s ignored bus system, largely used by lower-income commuters who lived in areas where the flashy new urban rail system which used up public transit funds did not venture. This differential of mobility access is one which was a manifestation of numerous historical injustices which led to starkly spatial impacts. To bridge across disparate geographies, the community organizing of the Bus Riders Union drew on historical practices of labor unionism, and drew from the same legal and spatial arguments as the “separate but (un)equal” logic of segregation: spatial divisions ultimately lead to spatial injustices. The Bus Riders Union and its activism led to reinvestment in the bus system even as rail expanded, and demonstrated that justice need not be the work of a balkanized few nor lead to zero-sum outcomes.

Soja, being a distinguished professor at UCLA, then focuses his attention on the role that educational institutions can play in this fight for spatial justice. He provides a few insights that were informative for the development of urban humanities. First, the strategies and tactics used by activists are valuable skills that can be taught and practiced in the classroom for any range of projects. These skills set students up to be well rounded citizens, provide skills that are a selling point for entry into public-sector or non-profit employment, and, beyond this, allow teaching and learning to move past abstract or theoretical concerns within a classroom and instead have a real impact on making the world around us a better place. Second, many other theories and skills which have long been taught in the classroom find new life and meaning for students as they become actualized in the “real world.” In particular, queer, feminist, and critical race theories are seen in real time as spatial injustices are identified and engaged with through action in a kind of Deweyan “learning by doing” (Dewey, 1916). Third, the importance of understanding and engaging with spatiality within contemporary life is made clear. This has led students to learn an array of complementary skills, ranging from cartography and geographic information systems (GIS), to critical spatial analysis of contemporary phenomena, to connecting the relationship between spatial justice and urban and regional development and transformation. These skills are highly valued in a range of contexts and set students up for a wide range of vocations, most of all those that deal with spatial justice. In short, spatial justice has become a lens through which urban humanities work is structured and understood, but it has also become an organizing principle for what kind of learning should take place, and this learning has served students well even beyond the classroom.

The practical future

The practical future is a concept that we later identified in relation to the scholar Hayden White’s writing on “the practical past.” In his work, he has noted how the professionalization and development of the writing of history has transformed historical work into something that is primarily done for other historians, in contrast with the age-old practice of history which has emphasized the practical and public importance of learning from our past so that we can collectively make informed decisions about the future (White, 2014). We noticed, as our varied disciplines joined together, that many spheres of scholarly work had largely shied away from engagement with the future. To engage with the future was too much of a risk, it was too speculative, while the present and past provided firmer footing for scholarly engagement based on fact and evidence. Yet the future is perhaps the most critical thing of all: why else would anyone need all this knowledge if not to use it for informing how we ought to act and bring to life new, more spatially just futures? Those disciplines that did engage the future, perhaps most notably architecture and urban planning, often did so in a way that was to promote flashy new designs or plans for the future that lacked context, historical or otherwise. Philosopher Walter Benjamin’s famed description of the “angel of history” experiencing “progress” (1968) serves as a kind of warning against these two opposite yet equally dangerous practices, with one’s gaze fixed upon the past even as powerful forces drag it into an unknown future, sight unseen, any sense of agency abandoned. Urban humanities, then, sought out to define something like the inverse of White’s “practical past,” a future-oriented scholarly practice that rigorously engages past and present so that we can collectively and intentionally move into the kind of future that we want.

Two related ideas form the basis for this kind of scholarly practice. The first we describe as the “generative imperative” — a kind of ethical call to action for teachers and scholars to engage seriously with the practical future, even though it may be risky or dangerous. The greater danger still, in our view, is to ignore the future altogether, unwittingly becoming the angel of history. The creative and speculative, when introduced to collaborative scholarly work, has the potential to push beyond solitary visionings of one’s desired future, or fatalistic imagining of the horrible futures that are to come, but, rather, collective dreaming of a future that we can begin working on building together. The second we described early on as “immanent speculation,” which is the “how” for those attempting to work in this manner, to “practice the future” (Crisman, 2016). There is a wide world of speculative practices, including continental philosophical approaches, speculative fiction, critical design, urban planning, architecture, or, not least of all, financial speculation. Each has its own qualities that are foregrounded in service of thinking or making the future, from science fiction’s emphasis on playing out the logical possibilities embedded into scientific discoveries, to the tectonic and material constraints of architectural design. For immanent speculation, the most important quality is the idea that the future is hidden in plain sight, immanent within our past and present. Immanent speculation demands rigorous analysis of the present and past in order to speculate about the future: cultural studies, anthropology, history, the wide array of humanistic and social scientific knowledge is brought to bear on our thinking of the future. Thus, we introduced speculative work that brought together the historical and critical capacities of the humanities with the future-oriented design thinking of planners and architects — and would invite even wider circles of scholarly practice into this stance of looking back and forth, from past, to present, to future. The speculative work that we propose in urban humanities is not ungrounded utopian imaginings but, rather, rigorous and thoughtful engagement with the past and present such that better, more just futures can be identified, extracted, and manifested from them.

Practices of urban humanities: thick mapping and filmic sensing

What is the methodology for immanent speculation in the service of spatial justice? I am certain that there are a multiplicity of as-of-yet undiscovered means for scholarship which operates under these values, but given the specificity of our positionalities and those of our collaborators, and of our shared experiences, we developed a few practices that served us well in this direction — practices which could also be expanded and refined further. In other words, the particular capabilities, experiences, disciplines, and questions asked by any collaborative group should result in the development of a unique set of working practices which may or may not evolve into more established methodologies. In this way, we refer to our scholarly approaches in urban humanities as practices because of their nascent, evolving, and undisciplined (as in not linked to any one particular disciplinary tradition) nature. Nevertheless, important qualities for these approaches included two key elements: First, they incorporate spatiality in some capacity so that spatial justice or injustice can be documented, analyzed, and re-envisioned. Second, they incorporate a recursive process of collaborative making where the practice and the outcome become intertwined. For example, map making is both a process of scholarly work which demands critical analysis as the mapping takes place, and is a scholarly output that can then communicate these analyses. This eye toward the realities of making within creative scholarship also become important to satisfy the generative imperative, allowing for speculative work in the same format and context as documentary and analytic work. I will describe two such practices that we found especially useful in the context of urban humanities, each of which might be described as a kind of spatial ethnography. Spatial ethnography involves the combination of the long tradition of ethnography, vast and diverse in its various manifestations, from sensory and video ethnography to more traditional textual forms of embedded observation, but with the key organizing principle of space rather than time. While spatial ethnography could also be considered a kind of third practice in its own right, it is also a broader and more capacious category that could also describe the following two practices.

Thick mapping

The first practice is that of *thick mapping*. Thick mapping draws from the lineage of critical cartographers who first began critiquing maps as objects which were so often seen as objective representations of reality but, in fact, were laden with biases of the map maker, just as any other medium produces cultural objects that are anything but purely objective representations of our world (see, for example, the writings of J.B. Harley, 2002; Denis Cosgrove, 2001, 2012; Denis Wood, 2010; Jeremy Crampton, 2011; or John Pickles, 2004). These geographers went even farther to note the map’s history as an object used by the state to enforce its power, whether it be from the earliest ancient cadastral maps used for identifying territorial claims for the purposes of taxation, to the objectives of colonizing powers during from the 14th century onward who laid claim to faraway lands and peoples. Thick mapping is a practice of mapping originating in the cultural emphasis of the humanities which responds to these critiques through new forms of mapmaking. The thick map is “thick” in sense of ethnographer Clifford Geertz’s practice of “thick description”: to capture spatial phenomena in a map is also to demand that the mapmaker practice critical interpretation of multiple layers of meaning, layers which may, at times, even be at odds with each other (Geertz, 1973). A thick map reveals the hand of the mapmaker and remains open to extension and modification, rather than purport to be a finished, neutral, objective representation of reality (see Fig. 2).

Further, a thick map, as an attempt to represent the palimpsest-like nature of space and place, strives to incorporate the multiple, interconnected, and yet conflictual layers of time, voice, meaning, and history — which are typically collapsed down to flattened, singular layers which erase entire communities within conventional mapping practices. This idea is ever more important as digitally

Fig. 2 Experiment in “thick mapping” on the issue of migrant death in the US-Mexico borderlands, showing the recovery and return of discovered remains from the Sonoran Desert to the Pima County Office of the Medical Examiner. Created by the author.

enabled mapping tools such as Google Maps have now become a kind of naturalized vision of our world, even as it remains as constructed as any other medium, reliant on idiosyncratic coordinate and projection systems, and drawn using largely arbitrary if widely accepted representational standards. The process of thick mapping is, itself, an experimental research praxis which uses spatial ethnography to collect data, placing that data into topological relationships within the cartographic frame of the map, self-reflexively critiquing, interpreting, and analyzing the object even as it is being made, then recursively adding, extending, iterating, and inviting others to do the same. In this way, thick mapping is both process and outcome, research and teaching, singular and collective, striving to fully capture the richness of the world within the map even as that impossibility is acknowledged at the outset. The thick map typically exists in concert with other forms of media, perhaps oral or written storytelling, or even as a series of maps extracted from a single mapping project, in order to narrate particular threads contained within the map, and to grapple with the complexity and illegibility that comes with the attempt to spatially capture the infinite nature of urban space. One global scholar whose maps demonstrate the “thickness” of the sidewalks of Ho Chi Minh City is Annette Kim, eloquently represented in her book *Sidewalk City* (2015).

Filmic sensing

The second practice is that of *filmic sensing*. Filmic sensing is something of a hybrid between the spatial ethnographic techniques of visual and sensory ethnography which use a camera as their tool and the speculative, generative, creative, and open-ended nature of the essay film. Filmic sensing involves the use of a camera to mediate, destabilize, and estrange our normalized vision of the world around us in real time. It acts as both a strategy for critical examination of space and, at the same time, as a means to visually capture these spatial and ethnographic observations for further exploration, editing, and interpretation — once again, it is both process and output. Filmic sensing, in fact, owes much to the historical origins of film as a medium: many early motion pictures were short clips of urban life. Urbanized life itself was developing as a novel and strange phenomenon just as the technology of motion picture film capture was introduced. In a way, the development of film and television has neatly tracked our global transformation into an urban society. Indeed, several remarkable early films were categorized within the newly coined “city symphony” genre of the 1920s, from Walter Ruttmann’s *Berlin* (1927) to Dziga Vertov’s *Man With A Movie Camera* (1929). These city symphony films bear key connections to the essay film genre, including their experimental formal qualities, non-linear narrative structure, and auteurist production process. Of note here is the example of Chris Marker’s *Sans Soleil* which combines speculative epistolary writing with documentary footage from disparate global locations (among other elements) to create a whole that is decidedly more than the sum of its parts, critically examining the human condition. Another contemporary global scholar whose work demonstrates filmic sensing is J.P. Sniadecki, providing an immersive ethnographic gaze into specific places throughout China, from public parks (Cohn and Sniadecki, 2012) to railroads (Sniadecki, 2014).

There are a handful of additional practices that we experimented with and found useful in different ways, from digital and multi-media installations to socially engaged art practices, and I am certain that there are myriad additional practices for working through urban humanities in ways that enable collaborative scholarly and pedagogical work that keeps a critical eye toward the future and toward spatial justice. Nevertheless, these two practices of thick mapping and filmic sensing were especially generative for our group, because of one key reason. They produced a space for collaborative creation and critical engagement (i.e., through the map or the film) that was capacious enough to incorporate both rigorous scholarship and creative or speculative impulses, yet was not methodologically predefined to such a degree that one collaborator or another could claim ownership or control over the process and outcome. This goes back to Fischer’s idea of the “symmetry of ignorance” (2000): the moment one particular methodology that is tied to one particular discipline (say, econometrics, for example), the immediately the collaborative process breaks down, the research questions become limited, and the ability to experiment and explore is curtailed. Urban humanities greatest contribution, perhaps, is the openness that comes with an experimental research praxis, allowing for deep collaboration and engagement across the infinite array of interlocutors that hold knowledge about some small piece of the city.

Urban humanities, its future, and you

The initial burst of urban humanities work and thinking owed much to the freedom afforded by the Mellon Foundation funding, which allowed us time and space to work with each other even though much of this activity did not fit neatly into institutional structures and expectations at UCLA. It provided organizational support, compensation for community partners, funding for student travel, and more. As funding has tapered off, the work has continued, yet in a way that has more constraints, tying more neatly into institutional structures, or focusing on more local travel and collaboration, for example. Mellon-funded initiatives at other universities have also, for the most part, either narrowed their scope to things such as post-doctoral research support, or are working to establish some kind of long-term institutional structure, such as the Future Histories Lab at UC Berkeley (2022). But beyond these efforts, the most promising future for urban humanities lies in the people it has engaged: over a hundred students have gone through this community-engaged research curriculum, experiencing a different way of doing scholarship from the typical solitary disciplining that occurs in conventional degree programs. These students are now doing work on their own, becoming teachers, or architects, or other kinds of practitioners who see the potential of bringing together past, present, and future in creative and critical work, in pursuit of spatial justice.

In one such example, two past urban humanities students, Jacqueline Jean Barrios and Kenny Wong, a literary scholar and architect, respectively, took the ethos of urban humanities to undertake a project which brought together experimental and creative research and pedagogy to uncover the intimacies between, of all things, philosopher Walter Benjamin's writing on the "ragpicker," artist Laura Grace Ford's zine series *Savage Messiah* (2006–9), Dickens's *Barnaby Rudge*, and the pivotal historical moment of the 1992 Los Angeles Uprising (Barrios and Wong, 2020). Their participatory method brought together researchers, students, and public to build a mental scaffolding between literary and artistic sources and the experience of the LA Uprising through the practice of "sonic scavenging," bringing new awareness to issues of race and policing and, at the same time, creating new practices of memory and commemoration. Their example demonstrates the potential not only of urban humanities, but of the humanities at large as a vital form of practice and engagement for public needs, especially in our broader historical moment of political division and social stratification where the humanities are maligned as not being "useful" enough for preparing workers in the capitalist economy. And all of this is to say nothing of the faculty, staff, and community partners who also collaborated under the auspices of urban humanities. I, myself, have moved on from UCLA to take a position in the newly established Department of Public & Applied Humanities at the University of Arizona, and have found extraordinary collaborators and potential in like-minded people working through the constellation of other experimental humanities fields, such as environmental or digital humanities.

So, I would like to conclude with an invitation: take urban humanities and make it your own. This work is unfinished, and it demands the hands and minds of participants beyond our initial group. The future of urban humanities is one that, by definition, will always be unfinished, open ended, extensible, so that it can engage the continual changes of our collective urban life. As more people bring their experience and creative capacity to collaboratively work across difference, bridging the kinds of knowledge and practice which make us human with spatial and urban studies, the better we will be able to contend with our unknown yet shared future. The practices described in this short article are an invitation for you try them out, to collaborate with people unlike yourself, with people in different social spheres, whether it is within or outside of spaces of learning, to be uncomfortable together so that you can co-create new media, analyze your surroundings, envision possible futures, address spatial injustices. If you do this, then you will be doing urban humanities. Who knows? Perhaps you already are.

Acknowledgements

Thanks to my urban humanities co-conspirators at UCLA, Dana Cuff, Anastasia Loukaitou-Sideris, Todd Presner, and Maite Zubiaurre, and to the Mellon Foundation for its generous funding of this work. Thanks also to the editors of this volume, David Yaden and Theresa Rogers, for their critical insight and feedback.

Chapter overview

Our focus in this chapter is to document the ways writing is described and researched by scholars in the field of literacy education. Specifically, we explore the writing process as viewed through scholarship that uses [Deleuze and Guattari's \(1980/1987\)](#) concepts of rhizomes, maps, and tracings to theorize potential entanglements in reading-writing relationships. In doing so, we are careful to avoid imposing these two French philosophers' thinking as if it were a mere grid-like framework in which to analyze the entanglements of reading and writing. From the start, we have heeded [Leander and Rowe's \(2006\)](#) insight that Deleuze and Guattari's ideas are best used to "spark our thinking in new directions.... [such that literacy in use involves] generating new ways of connecting texts, modalities, and performed identities" (pp. 432–434). For example, by using Deleuze and Guattari's concepts of rhizomes, maps, and tracings to rethink how writing and reading are entangled, emergent, and ever-becoming, we created an analytic method that combines traditional expository prose found in academic literature reviews with our narrativized accounts of literacy in use—that is, the *doing* of writing in relation to reading.

Rhizomatic mapping: concept as method

According to [St. Pierre \(2016\)](#), in a time of renewed interest in empirical inquiry, researchers trained in conventional humanist qualitative inquiry find themselves in need of language that decenters epistemology (i.e., *what* constitutes knowledge/known) to make room for ontology (i.e., *how* such knowing becomes 'reality'). To address that need, St. Pierre points specifically to a Deleuzian belief that language is action, a way of doing things with words. Inspired by this call for action, literacy researchers have used rhizomatic mapping as a spatial method for studying a range of literacy events involving texts. Among numerous examples, mapping has been used to look closely at adolescents' appropriation of popular cultural texts when re-negotiating their own identities ([Hagood, 2004](#)); to both situate and trouble literacy practices in Christianity's faith-based schools ([Eakle, 2007](#)); to analyze electronic poetry ([Evans, 2014](#)); to reread a pedagogy of multiliteracies ([Leander and Boldt, 2012](#)); and to conduct a non-linear analysis of a shared parent-child literacy event ([Yaden, 2004](#)).

Part of the creativity in mapping disparate phenomena at the surface level involves reading broadly in areas related to one's topic of study. For this chapter, we read in cultural studies and critical methodologies, including articles such as [St. Pierre's \(2013\)](#) explanation of how a Deleuzo-Guattarian ontology, which does not assume a subject/object binary, requires researchers to think differently about the concept of data. So differently, in fact, that Deleuze and Guattari (1987/1980) deemed it necessary to state explicitly why subject/object and human/material oppositions cannot be thought or lived:

We are not separate from the world. Being in every sense is entangled, connected, indefinite, impersonal, shifting into different multiplicities and assemblages. Our work is not "to reach the point where one no longer says I, but the point where it is no longer of any importance whether one says I." (p. 3)

We also drew from earlier research on inequitable literacy practices involving muted voices, silent texts, and cultural representations ([Alvermann, 1993, 2000](#)). The first of those two studies resulted in an in-depth literature review that became the author's

presidential address at the 42nd annual meeting of the National Reading Conference (now renamed the Literacy Research Association). Published as part of the proceedings for that meeting, it was Alvermann's first attempt at creating historical-autobiographical methods for uncovering silences, thus keeping literacy research and scholarly writing from masking more than they disclose. The second publication was a rhizomatic re-accounting of findings from her earlier research on adolescents' perceptions and negotiations of literacy practices while participating in after-school Read and Talk Clubs at a local library (Alvermann et al., 1999).

From Deleuze and Guattari's perspective, it is how texts function in relation to each other—often beyond themselves—that is of particular interest. This interest stems from their view that texts, like rhizomes, connect with other things. For instance, "a rhizome ceaselessly establishes connections between semiotic chains, organizations of power, and circumstances relative to the arts, sciences, and social struggles" (p. 7). Deleuze and Guattari's metaphoric use of the terms *maps* and *tracings* is this: a map is "a part of the rhizome ... open and connectable in all of its dimensions ... [with] multiple entryways, as opposed to the tracing, which always comes back 'to the same'" (p. 12). Maps, unlike tracings, are always becoming; they have no beginnings and endings, just middles (Deleuze, 1995). It is by looking at the middles that one begins to see how, in perspective, everything else changes. Dimitriadis and Kamberelis (1997) explained the process this way:

In drawing maps, the theorist works at the surface, "creating" possible realities by producing new articulations of disparate phenomena and connecting the exteriority of objects to whatever forces or directions seem potentially related to them. As such, maps exceed both individual and collective experiences of what seems "naturally" real. (p. 150)

Looking for middles, rather than beginnings and endings, also supports the decentering of key linkages in texts. Such decentering invites researchers to remain open to proliferations of rhizomatic ruptures and discontinuities, which in turn, endlessly create other linkages. For these reasons, Grosz (1994) argued that it is no longer appropriate to

ask what a text means, what it says, what the structure of its interiority is, how to interpret or decipher it. Instead, one must ask, what it *does*, how it connects with other things (including its reader, its author, its literary and non-literary context). (p. 199, emphasis added)

Finally, because we rely on narrative writing as part of the mapping process, it is fitting we conclude this section with a brief rationale for using that particular genre. According to Joseph Featherstone (1989), "the telling of stories can be a profound form of scholarship moving serious study close to the frontiers of art" (p. 377). Contemporaries of Featherstone (e.g., hooks, 1990; Lawrence-Lightfoot and Davis, 1997; Richardson, 1997) critiqued the notion that scholars should ever assume authority for telling other people's stories. Mindful of their critique, we offer rhizomatic accounts—or stories if you will—that are not of other people's telling; instead, they are of our own making. A major impetus for doing so is Brandt's (2015) *The Rise of Writing: Redefining Mass Literacy*. Brandt wrote it to provide an easily accessible text on her seven-year research project in which she interviewed 60 workaday adult writers. A separate set of 30 interviews involved participants whom she described as writing-intensive young people from 15 to 25 years of age who identified as authors of fiction, poetry, nonfiction, and journalistic writing. Based on findings from both sets of participants' data, Brandt claimed that writing is overtaking reading to become the more frequently applied language art in literate people's day-to-day activities. We offer such evidence not as an argument for moving reading over so that writing can take its place, but instead as support for choosing to report our rhizomatic findings as counternarratives on the ways writing has been described and researched by scholars in the field of literacy education.

How researchers have imagined writing

Smith (2019) captured various theoretical dimensions of writing since the late 1800s by using the metaphor of *waves* to characterize how these dimensions emerged, overlapped, evolved, and to some degree still linger. The product dimension is the first she noted, wherein people believed writing samples could indicate a person's cognitive abilities and developmental stages. Gradually, as thinking transitioned from product to process, researchers emphasized prewriting, writing, and rewriting as being key to one's literacy development. The practice dimension ushered in the importance of social interaction and environment, such that studies of the role writing can play in identity formation gained prominence. Building on those ideas, the pathways dimension highlighted writing as a multidimensional activity bound up with social, cultural, and environmental factors. In describing these dimensions, Smith made clear that ideas evolve over time in a nonlinear way. Thus, certain ideas endure and continue to be influential in research and practice.

In this chapter, we adapt Smith's (2019) use of the term *waves* to capture changes in how reading-writing relationships have been imagined by researchers over time. We acknowledge up front that these shifts have been neither linear in direction, nor totally separate from one another. We use the wave metaphor to denote what the action-verb of writing is. More pointedly, what writing *shows*, what writing *follows*, how writing *helps*, and what writing *does*.

What writing shows

The belief that writing can indicate a person's cognitive ability is pervasive. Smith refers to this idea as the product dimension, and although it was historically the first that she was able to locate, it is still an idea that is prevalent in 21st century literacy practices. The product dimension positions writing as a product that serves as evidence or demonstration of intelligence, learning, or more broadly, cognitive ability. This wave of thinking is the basis for much of contemporary assessment practices. Standardized testing creates writing samples that represent benchmark skills against which an individual's writing is judged. Such assessments often rest on the assumption that there are fixed cognitively related developmental stages through which a writer must pass in order to gain mastery. Consequently, it is not uncommon for assessments alone to be the driving force behind researchers' interests in designing studies that measure what writing can show. For instance, Swain et al. (2010) relied on prominent feature analysis to demonstrate how standardized writing assessments can support classroom writing instruction. By analyzing on-demand writing from state assessments, Swain et al. were able to identify 32 prominent features (e.g., sentence variety, hyperbole, and faulty punctuation) that correlated with higher scores on a state's writing assessment.

Beyond their usefulness in assessment-inspired studies, products from writing instruction also serve as indicators from which to draw conclusions about literacy related learning. In one such study (Nippold et al., 2005), persuasive writing samples representing writers from early childhood to adults in their mid-20s revealed how writers' argumentative strategies change over time. Even when researchers design studies to focus on multimodal storytelling within a New Literacies framework (and its emphasis on the social practices of literacy), options still exist for (a) relying on the logic of product analysis, and (b) drawing implications to show support for various writing standards in the Common Core (Chisholm and Trent, 2013). In short, writing that shows a connection to measurable end products retains a highly visible position in linear and ordered systems of thinking.

A counternarrative

In questioning the viability of systems that constrain writing as an end product, we offer a rhizomatic account of what a product-oriented analysis may have concealed in the Chisholm and Trent (2013) research report. Their study of a high school English class's use of digital storytelling to understand the literary element, place, centered on one focal student, Riley. Her final project served as their primary unit of analysis for identifying which of the standards (e.g., elements, visual composition) aligned with her story. Said another way, the researchers used Riley's multimodal text to create a tracing of how her work connected to the Common Core. This reverence for a "product" as well as the assumption that Riley's mastery of certain standards signified an "end" of learning prompted us to recall Deleuze and Guattari's (1987/1990) observation that "A map has multiple entryways, as opposed to the tracing, which always comes back 'to the same.'" The map has to do with performance, whereas the tracing always involves an alleged "competence" (pp. 12–13). Referencing the Common Core and Riley's so-called competence in demonstrating a degree of mastery over certain writing standards symbolizes how researchers (and yes, Casey and I as teachers) can comfortably arrive at unexamined conclusions.

Using rhizomatic mapping to reframe the Chisholm and Trent study, we envision entryways into Riley's writing as signifying middles, not beginnings and endings. Putting the tracing back on the map, as Deleuze and Guattari suggest, frees us to ask how else Riley's work connects to the real world. The last line of her digital story, placed next to a family photo and a picture of her home, jumps out at us: "[The bird's nest] reminds me of my own family, and how we used to be. I let a drawn out sigh, and realize ... I am home." Riley orients her story in a middle space—referring to memories and the past, but also descriptive of the present. A rhizomatic mapping lets us observe Riley describing her understanding of place in this excerpt of an interview from the Chisholm and T. study:

Yeah, like at the beginning, I thought that place was like, okay, this library is a place, outside is a place, you know. Everything is ... you're just there. Your place. That's where you are. But now, after [Ms. Trent] taught me about place, I realize that it is what's connected to you at the heart, not just any random spot in the world.

Riley reports that this writing project helped her understand how her connections make place significant, helping her to map her home in relation to the objects, nonhuman beings, and people that she associates with it. To summarize, a partial rhizoanalysis of Chisholm and Trent's research reveals how writing facilitated a change in Riley's perspective that was not captured in the researchers' end-product analysis. It also facilitated a closer look at how Riley was making connections between place and things that are important to her.

What writing follows

Correlational studies of reading and writing suggest a hierarchical arrangement in the cognitive realm—one in which reading leads and writing follows. However, that was not always the case. Prior to Tierney and Shanahan's (1991) landmark review of research on the relationships between reading and writing, there had been decades in which these two cognitive processes were treated as separate entities residing in different academic spheres. Indeed, it took what Gee (1990) termed 'the social turn' to disrupt the status quo.

In Alexander and Fox's (2019) historical analysis of the literacy field, the move away from research dominated by cognitive models of reading and writing to sociocultural models occurred roughly between 1986 and 1995. The conditions for such change included an increased "acceptance in the literacy community of ethnographic and qualitative modes of inquiry advocated in social and cultural anthropology" (Alexander and Fox, 2019, p. 43). While many literacy researchers in the sociocultural era focused on the interrelated nature of reading and writing, they often framed writing as an activity that follows reading. That wave of research relied heavily on correlational studies to predict reading competency based on certain types of writing skills.

Although correlational studies of literacy were most common in the 1960s through the mid-1980s, this approach to inquiry continues. For instance, researchers of two such studies (Allen et al., 2016; Allen et al., 2019) reported mixed results when studying whether or not writing flexibility in argumentative essays predicts reading comprehension. Ideologically, this kind of research supports what social anthropologist Brian V. Street (1995) labeled the autonomous model of literacy—one predicated on the assumption that reading and writing are neutral processes devoid of relations of power—whether due to socioeconomic, cultural, or political influences. In extending Street's critique of the autonomous model of literacy, 21st century activist researchers Byrd et al. (2021) call for composition studies whose purposes range from "engaging marginalized communities to taking up matters of policy or direct action" (p. 16).

No counternarrative

We refrained from attempting a rhizo-analysis of the two correlational studies mentioned above. To have done so would have been a contradiction of Deleuze and Guattari's (1987/1990) thinking. Although correlational research is capable of teasing out entangled relationships between reading and writing, the use of statistical measures to represent those relationships would produce a report that is more akin to tracing than mapping. Indeed, replications of a tracing (one after another) can lend added confidence that a relationship is "real" and worthy of implementation. Minus a mapping that keeps multiple variables in play, a researcher cannot readily think the impossible. Nor can the literacy rhizome rupture freely when it's constrained by a paradigm that prefers wrapping up messiness to letting it flow.

What writing helps

A significant question to have emerged from the Center for the Study of Reading (CSR) at the University of Illinois, Urbana-Champaign in the late 1970s through the 1980s was whether or not findings from basic research conducted on the cognitive processes underlying text-based reading comprehension had application in classroom-based instructional research, particularly as it applied to reading and writing instruction. This was the question that drove the National Reading Research Center's agenda—a collaboration between the University of Georgia and the University of Maryland. The NRRC was federally funded by a five-year (1992–1997) grant from the U. S. Department of Education Alvermann and Moje (2019). Shortly after findings from the NRRC's classroom-based instructional research were disseminated through published articles and associated instructional pamphlets aimed at teacher implementation, a relatively small but robust body of literature sprung up around the use of strategies that situated writing as a helper in promoting readers' responses to literary texts through guided journal writing (Wong et al., 2002) and literature logs (Saunders and Goldberg, 1999). On occasion, large-scale research projects, such as Graham and Hebert's (2011) meta-analysis of writing and writing instruction's impact on students' reading, have offered hope that writing would grow out of its subsidiary role as helper and occupy an entity worth studying for its own sake. Although Graham and Hebert focused their 2001 meta-analysis on writing, giving hope that writing would get the attention it deserved, the research questions still positioned writing in a helping relationship to educational outcomes. They questioned if an increase in writing improved reading comprehension, and specifically looked at whether writing about class readings improved understanding of those texts.

In that same vein, proponents of novel study—a boutique-like research domain that focuses on writing in relation to literary works—appeared. But even so, one can find traces of the helper role infiltrating writerly aspects of novel reading. For instance, sometimes specific instructional writing strategies used during literary novel study can end up being evaluated by reading comprehension assessments or adapted for use in writer's workshop (Tracy and Headley, 2013). Findings from one such study, an intervention called Reader Response Plus Granger et al. (2007) caught our attention because key participants, all of whom experienced disabilities related to reading, wrote in their journals after reading portions of a class novel to prepare for group discussion. Granger et al. used a common informal assessment, the Qualitative Reading Inventory (QRI), to measure change from pre-to post-intervention. The researchers reported that each student's comprehension level showed improvement. We were curious, however, as to what else might have been a learning outcome of Reader Response Plus.

A counternarrative

Entering that study's parameters as researchers and educators grown wary of how tracings from one curricular reform after another have returned us to the same place, we nonetheless set out to explore potential discontinuities, even ruptures, that might put us on a different pathway for dealing with the subjugation of writing by reading. In the rhizo-analysis we've temporarily tagged "The Status Quo," we question to what extent assessments (even informal ones such as the QRI), are tracings of what students at different

ages and grade levels **should** be able to do instead of maps of what they are **actually** doing when tracings aren't there to blunt creativity and the joy of breaking off to go in a different direction.

Another opportunity for pushing back on the status quo comes from the intervention's reliance on journaling and discussion—the middles rather than the typical pre- and post-assessment activities. It's as if writing has backed off its traditional role of helper to become playfully complicit in the writer's plan for novel study. Indeed, there is some empirical evidence to suggest that rhizoanalysis is not restricted to mere theorizing. For example, information in the form of observations that teachers were making about one of the case study students, David (a pseudonym), showed that initially he didn't like the class novel, but gradually began sharing more about the book in discussions with his classmates. Separately in the article, the researchers noted, "The teacher attributes the increases in personal connections made to the novel by all students as largely due to David's modeling. He began to connect personally with the book through journaling, regardless of the prompt. After hearing his personal stories, other students began to follow by example." Although Granger et al. do not mention it, we tend to give at least partial credit to writing's easing away from its helper role. In short, writing took on a quasi-facilitator's role rather than that of a lowly gatekeeper.

What writing does

In this, the last wave of our action-verb for what writing is, we envision its entanglement with reading in much the same way that [Bloome and Green \(2015\)](#) described the inseparability of literacy and the people who use it. In their words, "Literacy cannot be separated from what people are doing, how they are doing it, when, where, under what conditions and with whom they are doing it; metaphorically, there is no separation of the dancer from the dance" (p. 20). Further, because the example we use in this last wave is itself a creation derived from mapping sound, it is in part dependent on high-tech virtual interfaces for displaying what writing does. Far from being redundant, the rhizomatic analysis we use in constructing a counternarrative for this wave permits us to expand our thinking further by exploring potentially new offshoots.

That said, we remain focused on the ways in which literacy researchers are moving away from treating writing as the end product of a reading activity. In doing so, we note the considerable influence of [Stornaiuolo et al. \(2017\)](#) interest in mobilities on our own thinking. Specifically, their framework for inquiring into transliteracies pulls from Deleuze's concept of emergence: "the process by which unprecedented, unimaginable ideas come to be in the world" (as cited in Stornaiuolo et al. p. 77). Emergences, like rhizomes, are concepts that make it possible to construct counternarratives of what previously might have remained 'just findings' in reading-writing studies destined for dusty bookshelves (or worse).

Before going further into this introduction of what writing does, we need to acknowledge a branch of scholarship dedicated to understanding the intertextuality of writing and reading, particularly the way that writing becomes entangled with the textual worlds of the writer. Sometimes this research focuses on the connection between what [Dyson \(1991\)](#) calls "worlds and words" in writing and written language development. Working within these intertextual spaces, [Bloome and Egan-Robertson \(1993\)](#) examined the social nature of textual connections while [Dyson \(2018\)](#) focused on the impact of popular culture on young children's writing. As noted earlier, [Tierney and Shanahan's \(1991\)](#) review of the research on reading-writing relationships explored intertextual connections that we now credit with having foreshadowed the action term, writing that 'does'. Even earlier language and literacy researchers working with cognitive processing models for composing (e.g., [Brozick and Petrosky, 1979](#); [Flower and Hayes, 1981](#)) were careful to emphasize that writing deserved its own line of inquiry.

Finally, as evidence from [Brandt's \(2015\)](#) scholarship would suggest, writing is stepping out of reading's shadow and inserting itself into neighboring domains. For instance, one might say that writing has found a niche in the multimodal research on sound-writing ([Brownell, 2019](#); [Wargo et al., 2021](#)); imagery ([de los Rios, 2020](#)); touch ([Sanders, 2018](#)); dance ([Risner and Anderson, 2008](#)); and meme-ing ([Knobel, 2022](#); [Lankshear, 2022](#)). By entangling itself with modes that largely reject hierarchical logic and representational thinking, writing is becoming more and more an interpretive activity in its own right rather than simply evidence of that activity. We view [Wargo's \(2018\)](#) study of soundwriting as a good example of the transitioning process just described. Thus, portions of that study's abstract appear here as a way of providing context for our rhizomatic analysis of what soundwriting does.

In partnering theoretical insights from multiliteracies, queer phenomenology, and sound studies, Wargo underscores sound's capacity as a resource for adolescent multimodal writing. Refracted through a singular LGBTQ youth's practice of sonic cartography, the participant's counternarrative—comprised of notes, sounds, and neighborhood hand-drawn maps—expresses feelings of isolation in the midst of pressures to become part of a larger after-school gathering. Findings from Wargo's research suggest that sonic cartography is a form of (counter)storytelling in that it creates new ways of knowing and becoming. Wargo asks literacy researchers and educators to consider how rhizomatic stories that youth compose can turn up the volume on formal and informal literacy learning.

A counternarrative

Given the richness in multimodal writing research, why did we, as authors of a piece on trends in literacy education, settle on [Wargo's \(2018\)](#) study as our example? Mostly because Andi, a self-identified 17-year-old Latina lesbian, who delighted in calling herself a high-school dropout, was a participant in Wargo's ongoing longitudinal research project. Also, Andi was of interest because she

had access to open-source tools that she connected to her Instagram account—her composing tool of choice. Geotagging software allowed Andi to map sounds of injustice in various urban neighborhoods where she felt safe, not so safe, and/or an outsider.

We also were drawn to Andi's stance that tools for capturing video and sound provided all she needed for sonic compositions. We took Andi at her word and thus were surprised by the linguistic traces she left while mapping sounds and images at the core of her self-imposed silences. By using rhizomatic analysis to inspect Andi's sonic maps, we learned that reading and writing are inseparable literacy processes in the presence of sound and imagery. Evidence of Andi's use of three modes (sound, imagery, and language) coexist. For example, her sonic map of what she called "#MYSIDEWAYSSCHOOL" consists of what Andi heard when she audio-recorded "sounds.of.school" during her walks around the community college she attended. In her words, "you-hear=homophobia.misogyny.peoplethinkingweredumb" (p. 20) as a linguistic descriptor under an upside-down image she constructed of her college's welcoming sign. Andi attributed this positioning of the sign as a reflection of the friction she feels in attending the community college as a high school dropout" (p. 19). When we inspected her #hashtag assemblage using our literacy rhizome as an analytic, we could not detect a break or rupture in the rhizome.

Similarly, Andi's second sonic map, #SOUNDINGOUTMYSILENCE, was both an artifact and identity marker that she used in "indexing herself as a survivor of self-harm" (p. 20). In her descriptor text of the hashtag, she wrote:

you.didnt.hear.me.this.is.because.i.feel.voiceless
listen.mysilence.means.something
#selfharm.awareness.week. (p. 21)

Both assemblages viewed through a rhizomatic lens suggest that when writing assumes an agentic role, its "doing" potential is as predominant in the linguistic mode as it is in the sound mode. Still, Wargo (2018) argued persuasively, "As an audience, we hear the environment as it emerged. In short, Andi helped me discover how hearing difference is different from seeing or merely reading about it" (p. 21). Entangling these two modes, as Wargo (2018) has done, raises challenging questions—the most intriguing from our perspective being: (a) If writing is forging a new pathway in literacy circles as Brandt's (2015) seven-year research project would suggest, what added benefits will accrue to digitally literate youth, and (b), if such benefits widen the digital divide even further, what consequences might prevail?

Concluding thoughts

Although our focus in this chapter has been on the ways writing is variously described and researched by scholars in the field of literacy education, we cannot ignore the potential impact of researchers' assumptions about writing on actual classroom practice. From a pedagogical perspective, writing has historically been positioned, at least in contexts of schooled literacies (including doctoral studies), as an end product that follows reading. Writing serves as proof that reading comprehension of texts has occurred. Thus, it comes as no surprise that when reading-writing relationships are parsed—as if there exist actual beginning and ending points for the two domains—opportunities are few for experiencing movement between, among, and beyond texts.

Findings from our rhizomatic analysis of movement in reading-writing relationships are not carved in stone; quite the contrary. Accepting the unexpected (e.g., disruptions and new entanglements between writing and reading) is in keeping with Deleuze and Guattari's thinking (1987/1980). Not surprisingly, Honan and Sellers (2011) referred to rhizomatic analysis as a means of producing "(im)plausible readings" (n. p.), which was perhaps a spinoff from Spivak's (1996) earlier descriptor: "scrupulous and plausible misreadings" (p. 45). The figuration of a rhizome provided precisely what we needed to disrupt continua that signify beginnings and endings and/or cause-effect thinking in terms of reading-writing relationships. By interspersing rhizomatic maps (and the narratives they evoked) among conventionally written research reports (expositions), we were able to provide yet another example of writing's potential for 'doing' rather than simply assisting readers comprehend such reports.

In a rhizome, new shoots spring forth regularly, but these new growths do not totally abandon the rhizome, nor indicate a total rejection of shared ideas and connections. We value such emergences for their potential to erupt, rejoin, and erupt all over again. The more options the better. At the same time, we value Tierney's (2017) cautionary note regarding "meaning making in the labyrinth of multilayered text worlds" (p. 263). If meaning making manifests through internationally informed scholarship Andreotti and de Souza (2011) and draws from a broad range of human wisdom, then the rhizomatic eruptions we celebrated above are welcomed. On the other hand, if such eruptions serve to reify already established ways of thinking by dominant groups in the global western and northern hemispheres at the expense of equal representation in the eastern and southern hemispheres (Tierney et al., 2021), then we would need to reconsider the use of rhizoanalysis for learning how writing is taken up differently, say, by youth in North America (Rogers and Winters, 2010) as contrasted with youth in South Africa (Watson and Hugo, 2015). While valuing the potential for such cross-cultural differences to inform literacy research and at the same time agreeing with Tierney et al.'s call for global diversity in literacies research, we note a continuing issue that they also acknowledged in their call. Namely, as Hugo (2016) puts it, the need for radically rethinking the purposes of education more generally "in a world that is becoming increasingly unequal while global warming intensifies" (p. 11).

There is room for hope that involves scholarship in writing, though not of the kind that breeds complacency or a blind trust in writing that “does.” For is it simply that some writing “does” and some does not? Or is writing always “doing” but in ways that are not consistently recognized? We favor the latter explanation because it avoids thinking in binaries. Theory aside, writing that “does” is powerful writing, especially for those who have reliable, high-speed internet for networking; those without, regrettably, go without (Morrell and Rowsell, 2019) and pose a continuing issue for Tierney et al.’s (2021) manifesto on socioeconomic and political grounds. Based on our research, we maintain that differing perspectives, whether radical, moderate, or otherwise, can be materially dealt with when writing assumes a position of *doing* rather than *being done to*. Only then will moving away from treating writing as the end product of a reading activity achieve some degree of sustainability. Embracing writing and reading as an entangled literacy whose rhizome will continue to erupt and shoot off in different directions is movement—a condition favoring sustainable progress in the middles without the restrictions of beginnings and endings.

EDITORS IN CHIEF – BIOGRAPHIES

Robert J Tierney

Rob Tierney is an international educator whose passion is for developing research partnerships to address local literacy needs with educators in different countries. Rob began his career as a classroom teacher in Australia, then proceeded to work in the United States, Canada, Australia and China. He is Dean Emeritus and Professor Emeritus of Language and Literacy Education at the University of British Columbia, the former Dean and Honorary Professor of the Faculty of Education and Social Work at University of Sydney, and a Distinguished University Professor at Beijing Normal University. In the United States, he has served on the faculties of the University of Illinois, University of Arizona, The Ohio State University, Harvard University, and the University of California. Rob has written a number of books and numerous articles on literacy especially related to global issues, diversity, and literacy development. His most recent book was entitled *A History of Literacy Education: Waves of Research and Practice* published by Teachers College Press in 2021. During his tenure as an educator, he has served as the President of the International Literacy Association, President of the Literacy Research Association, an Editor for the *Reading Research Quarterly*, the President of the Association of Canadian Deans of Education/ L'Association Canadienne des Doyens et Doyennes d'éducation, as well on a number of committees and boards for professional groups and government and nongovernment

agencies. In addition, he has been involved on a range of groups on projects globally including in Africa and Asia including for UNESCO, Children's Television Workshop, and Apple Computer.

Fazal Rizvi

Fazal Rizvi is an Emeritus Professor of Global Studies in Education at the University of Melbourne, as well as at the University of Illinois at Urbana-Champaign. He is also a Visiting Professor at the Universities of Turku in Finland and Pretoria in South Africa. He has written extensively on issues of identity and culture in transnational contexts, globalization and education policy, and Australia-Asia relations. He has published widely, and his book, coauthored with Bob Lingard, *Globalizing Education Policy* (Routledge 2010) is used widely in courses around the world. A sequel to this book, *Reimagining Globalization and Education* (Routledge 2022) has been published recently. Fazal is currently researching educational reform in Bhutan. He is a Fellow of the Australian Academy of the Social Sciences, a past Editor of the journal, *Discourse: Studies in Cultural Politics of Education*, and a past President of the Australian Association of Research in Education.

**Kadriye Ercikan**

Kadriye Ercikan is Vice President of Research and Measurement Sciences at the Educational Testing Service and Professor Emerita at the University of British Columbia. She is responsible for ETS's foundational and applied research and psychometric support of ETS's major testing products and contracts, and the NAEP contract for ETS. Her research focuses on validity and fairness issues and sociocultural context of assessment. Her recent research includes validation of score meaning using response processes, use of response process data for comparing groups and examining fairness and validity of interpretation, and use of scores from artificial intelligence-based automated scoring.

Ercikan is a Fellow of the International Academy of Education. Her research has resulted in 6 books, 4 special issues of refereed journals, and over 100 publications. She was awarded the AERA Division D Significant Contributions to Educational Measurement and Research Methodology recognition for another

coedited volume, *Generalizing from Educational Research: Beyond Qualitative and Quantitative*

Polarization, and received an Early Career Award from the University of British Columbia. Ercikan has been selected to serve as the NCME Book Series Editor (2021–2026).

SECTION EDITORS

Jason Beech is Associate Professor (Global Policy) at the University of Melbourne and visiting professor at Universidad de San Andrés in Buenos Aires where he holds a UNESCO Chair in Education for Sustainability and Global Citizenship. He is senior researcher of the National Council for Scientific and Technical Research of Argentina (CONICET), and Associate Editor of *Education Policy Analysis Archives*. He has been a member of the Board of Directors of the Comparative and International Education Society (2014-2016). Jason has published extensively on the globalization of knowledge and policies related to education. He has also written and is passionate about the challenges of educating for global citizenship and a sustainable future. He has taught in several universities in the Americas, Europe and Australia.

Professor Qing Gu is Director of the UCL Centre for Educational Leadership and Professor of Leadership in Education. She is the Past Chair of the *British Association of Comparative and International Education* (BAICE), Co-Editor of *Teachers and Teaching: Theory and Practice*, Associate Editor of *International Journal of Educational Development*, a member of the Research Standing Committee of the World Council of Comparative Education Societies (WCCES), and a member of the Research Evidence and Impact Panel for the Leadership College for UK Government. Professor Gu has directed and codirected many government and research council funded projects in the areas of teacher professional development, school improvement, and systemic reform and change. She has led a £1.9 m UK Economic and Social Research Council (ESRC) funded project *Schools as Enabling Spaces to Improve Learning and Health-Related Quality of Life for Primary School Children in Rural Communities in South Africa*. Some of her books have been translated into Chinese, Japanese, and Spanish.

Professor Smith is a New Zealand Maori of Te Aitanga a Hauiti, Ngati Porou, Kati MamoeNgati Apa, Ngati Kahungunu descent. He is a highly regarded and internationally recognized, Maori educationalist and scholar. He has been at the forefront of transforming Maori and Indigenous social, economic and cultural conditions through re-developing education and schooling outcomes. His work links theoretical thinking and practical applications within an ongoing cycle of transforming praxis.

Professor Smith trained as a teacher at Auckland Teachers College and taught in Auckland schools. He also lectured in Education at the Auckland College of Education. He was one of the first teachers and developers of a Kura Kaupapa Maori, an alternative, Maori philosophy and principles-based School. These Maori immersion schools have grown from a single entity in 1988 to over seventy-five publicly funded schools in 2015. His theoretical leadership in the Education Department at the University of Auckland helped inform the emergence of Maori Education as a distinct field of study across the New Zealand Tertiary Sector. This work has encouraged a wide range of academic studies focused on overthrowing persisting inequities within and as a result of education and schooling in New Zealand. His significant contribution to New Zealand education is to be seen in his work related to Kaupapa Maori as a theory of Transformative Praxis. All of these elements derive from his PhD research entitled, "The Development of Kaupapa Maori: Theory and Praxis (1997)".

Professor Smith's later academic work centered on developing theoretically informed strategies related to transforming high and disproportionate levels of Maori cultural, political, social, educational, and economic marginalization. He has been a significant scholar involved in the emergence of Tribal "university" institutions (Wananga) and is the former foundation Chair of the Council for Te Whare Wananga O Awanuiarangi. He led the successful Treaty of Waitangi Claim and settlement for Awanuiarangi. In his former position as Pro Vice Chancellor (Maori) at the University of Auckland, he was responsible for developing significant structural change within the institution while working within the Office of the then Vice Chancellor, Dr. John Hood. Notable achievements included implementing a Maori development strategy within the University which required all Deans to be responsive in their performance results for Maori and Pacific advancement; the oversight of the Proposal and winning of a National Centre of Research Excellence (Nga Pae o te Maramatanga); the initiation of the Maori and Indigenous doctoral program aimed at creating 500 Maori PhD graduates across the country in five years; the recruitment of top Maori academic scholars into the University of Auckland; the development of Kaupapa Maori as a theory of transformative praxis and which has had national and international influence. Professor Smith also served on the University of Auckland Council for three years as the Professorial representative for Academic staff.

In 2007 Professor Smith accepted a role as the Universitas 21 Distinguished Visiting Professor in Indigenous Education hosted by the University of British Columbia (within the Faculty of Education). Although the position was initially intended for two years, the role was extended for a further three years. While situated at the University of British Columbia, Professor Smith also chaired the Educational Policy Studies Department for three years. These positions allowed engagement with many Canadian universities as well as other universities across the world.

Professor Smith has made significant contributions to the political, social, economic, and cultural advancement of Maori and indigenous communities in New Zealand and around the Pacific Rim. He has worked extensively with other Native/Indigenous/First Nation's peoples across the world, including in Canada, India, US mainland (including extensive work in Hawaii and Alaska), Norway, Taiwan, Chile, Australia, as well as with selected Micronesian and Pacific nations. He is a regular contributor to national and international forums and conferences. Professor Smith has been an authoritative voice within the critical debates on *social, cultural and economic inequality* both in New Zealand and abroad, and he maintains a strong influence in the Maori/Indigenous languages revitalization movements.

Professor Smith stepped down from the administrative position of CEO/Vice Chancellor at Te Whare Wananga o Awanuiarangi in 2015 after eight years in the role. He resumed his academic research and writing career. In 2019 he was invited to take up a special Chair – Te Toi Ihorei ki Purehuroa – A "distinguished Professorial position at large" established for him at Massey University.

Professor Smith has been recognized and honored for his international contributions, receiving an Honorary doctorate (D.Litt.) from the Okanagan University College in 2005, and an Honorary doctorate (LLD) from the University of Northern British Columbia in 2013; he was elected as a Fellow of the American Education Research Association in 2014, and was awarded a Queens Honour – a CNZM in 2014. He was given the Prime Minister's Life-time Achievement Award (2017); and received the Te Ururangi National Award for Education (Matariki Awards, 2019).

Professor Smith is married to Professor Linda Tuhiwai Smith and they have one daughter and two mokopuna (grandchildren).

Therese N. Hopfenbeck is Professor of Measurement Analytics in the Melbourne Graduate School of Education, The University of Melbourne. Before starting her position in Melbourne, she was Professor in Educational Assessment and Director of the Oxford University Centre for Educational Assessment. She is a Visiting Fellow at Kellogg College, University of Oxford, elected Vice-President of *The Association for Educational Assessment-Europe* and Lead Editor of the journal *Assessment in Education, Principle, Policy and Practice*. Dr. Hopfenbeck's research agenda focuses upon bridging research on self-regulation and classroom-based assessment and making sense of international large-scale studies in education. In collaboration with Professor Nancy Perry, University of British Columbia, she is currently leading an international network of researchers disseminating classroom-based research, funded by Social Sciences and Humanities Research Council of Canada (2020–2022). She is also currently Principal Investigator for two research projects funded by IB, on critical thinking in PYP schools internationally and evaluation of education reforms in Kent, UK (2020–2022). In 2020, she led the research on Critical Thinking in the Diploma Program in Australia, England, and Norway (<https://ibo.org/research/outcomes-research/diploma-studies/critical-thinking-skills-of-dp-students/>). Dr. Hopfenbeck was Principal Investigator for the PISA (2022) study in England, Northern Ireland, and Wales, in collaboration with Pearson UK (2018–2023). She was the Research Manager of PIRLS (2016), funded by The Department of Education, UK.gov, and Principal Investigator of a major ESRC-DFID research study, Assessment for Learning in Africa (ES/N010515/1) (2016–2019).

Since coming to Oxford in 2012, she has been the recipient of funding from ESRC-DFID, OECD, The Norwegian Research Council, Education Endowment Foundation, State Examinations Commissions Ireland, Jacob Foundation, and the International Baccalaureate totaling more than £2 mill in addition to a single grant of £4 mill in collaboration with SLATE: Centre for the Science of Learning & Technology at the University of Bergen, Norway. Prior to her appointment at Oxford, she worked as a postdoctoral researcher at the University of Oslo's research group for Measurement and Evaluation of Student Achievement at the Unit for Quantitative Analysis of Education (2010–2011). She is Adjunct Professor of the Norwegian University of Science and Technology (NTNU), member of the Visiting Panel for Research at the Educational Testing Service (ETS) in Princeton, expert member of the PISA (2022) Questionnaire Framework group, appointed by ETS and OECD (2014–2023). She has advised on the implementation of formative assessment programs in India, South Africa, Norway, and the Emirates and carried out policy work for UNESCO/OECD and the Norwegian Ministry of Education Norway. Therese has a presence on LinkedIn, ResearchGate, [Academia.edu](https://www.academia.edu/), and Twitter: @TNHopfenbeck.

Nataliya Ivankova, PhD, MPH, is Professor in the School of Health Professions at the University of Alabama at Birmingham (UAB). As an applied research methodologist working at the intersection of mixed methods, qualitative, community-based, action, and translational research, she is internationally recognized for her empirical and methodological publications. She shares her research expertise through teaching mixed methods and qualitative research courses, conducting workshops and guest lectures, mentoring doctoral students and junior faculty, and serving as key personnel on funded research projects. At UAB, she directs an online graduate certificate program in *Applications of Mixed Methods Research* and oversees the design and analytical aspects of qualitative and mixed methods studies through the Center for Health Informatics for Patient Safety and Quality. She is a founding Coeditor of the *Mixed Methods Research Series* (Sage) and serves as an Associate Editor for the *Journal of Mixed Methods Research*.

Professor Jahnke is Director of Toi Kura Centre for Maori & Indigenous Education. She was the 2019 inaugural Toi o Te Wananga Fellow. Professor Jahnke holds professional qualifications in education and is cofounder and immediate past Chair of the Indigenous Peoples of the Pacific Special Interest Group of the American Education Research Association (AERA). She currently serves on the AERA Executive Committee. She was a member of the Social & Human Sciences Sub Commission of the NZ National Commission for UNESCO, the NZ Bioethics Council, the NZ Ethics Committee on Assisted Reproduction Technology, and Chair of NZ Health Research Council Ethics Committee. She is currently Cochair of the Aotearoa Research Ethics Board and a Fulbright Scholar.

Berit Karseth, PhD, is Professor at the University of Oslo, Department of Education. Karseth's main research and publications lie in the field of education policy, reforms, and curriculum studies. She has edited four books and written several journal articles and book chapters in both Norwegian and English. Her most recent publications in English include articles published in the *Journal of Education Policy*, *Scandinavian Journal of Educational Research*, *Journal of Curriculum Studies*, and *European Educational Research Journal*. Karseth was the elected dean of the Faculty of Educational Sciences at the University of Oslo 2013–2016 and is currently in the leadership team of the research group Curriculum studies, educational leadership, and governance (CLEG) at the same institution.

Dr. Kenneth Leithwood is Emeritus Professor at OISE/University of Toronto and an honorary professor at the University College London and the University of Nottingham. His research and writing is about school leadership, educational policy, and organizational change. He has published extensively on these topics. For example, his most recent books include *Leadership Development on a Large Scale: Lessons for Long-term Success* (2018, Corwin), *How School Leaders Contribute to Student Success* (2017, Springer), and *Linking Leadership to Student Learning* (2012, Jossey Bass). Professor Leithwood is the inaugural recipient of the University of Toronto's *Impact on Public Policy* award, AERA (2011) *Outstanding Leadership Researcher Award*, the 2012 *Roald F. Campbell Lifetime Achievement Award* from the University Council for Educational Administration, and the Ontario Principals' Council *Outstanding Educator of the Year* award for 2017. He is a *Fellow of the Royal Society of Canada*. A recently published bibliometric analysis found that Dr. Leithwood was the most frequently cited, highest impact educational leadership researcher in the world.¹ Research.com's 2022 Ranking of the Top 1000 Scientists in the area of Social Sciences and Humanities ranked Dr. Leithwood 70th in the world and 7th in Canada.

Xiufeng Liu is a Professor of Science Education at State University of New York, Buffalo, and a Fellow of the American Association for the Advancement of Science (AAAS). He obtained his PhD from the University of British Columbia in 1993. Before his current position, he taught high school chemistry in China, and was a tenured faculty member at St. Francis Xavier University and University of Prince Edward Island, both in Canada. From September 2020 to August 2022, he served as a program director in the Division of Research on Learning of the National Science Foundation. Dr. Liu conducts research on measurement and evaluation of STEM education and student learning of cross-cutting concepts of matter and energy. Dr. Liu is currently a Coeditor-in-chief for the journal *Disciplinary and International Science Education Research* (Springer) and an Associate Editor for the *Journal of Research in Science Teaching*, a premier journal in science education.

Margie Maaka is a Professor of Education at the University of Hawai'i at Mānoa. Her PhD is in educational psychology. She also holds professional qualifications in education from the University of Waikato and Hamilton Teachers College. She is cofounder and current Program Chair of the Indigenous Peoples of the Pacific Special Interest Group (SIG) of the American Educational Research Association (AERA). From 2017 to 2020, she served as a member of the AERA Executive Council and Chair of the SIG Executive Committee. Before that (2014–2017), Professor Maaka served as a member of the SIG Executive Committee. She has also served as a member of the Ngā Pae o te Māramatanga Center of Research Excellence International Research Advisory Panel. Her research on community-based educational renewal saw her recognized as a national scholar with the Goodlad Institute for Educational Renewal. As Cochair of the Sovereign Councils of the Hawaiian Homelands Assembly's Committee on Education, she prepared educators and educational leaders for public schools in the Hawaiian Home Lands Trust communities. Currently, Professor Maaka is committed to the preparation of indigenous educational leaders in higher education. Her research interests include community partnerships, educational psychology/indigenous educational psychology, indigenous development and advancement, educational policy, multiliteracies, and language and cognitive development.

Diane Mayer is Professor Emerita at the University of Oxford. Her research and scholarship focus on teacher education and early career teaching, examining issues associated with the policy and practice of teachers' work and teacher education.

Daniel McCaffrey is the Associate Vice President of Psychometric Analysis and Research in the Research and Measurement Science unit of the Research and Development division at ETS. Dan's research interests include the evaluation of artificial intelligence scoring of constructed responses, developing tools and methods for causal modeling, evaluating the psychometric properties of student achievement growth measures derived from annual test scores, and methods to account for measurement error in secondary data analysis. Dan received his PhD in Statistics from North Carolina State University in 1991.

Judy Parr is Professor Emerita at the University of Auckland, Faculty of Education, where she was the founding Head of the School of Curriculum and Pedagogy. A psychologist, Dr. Parr's research program is located broadly within improvement science. Her expertise is in literacy, specifically writing and its development, encompassing instructional issues like teacher knowledge and practice and the assessment of writing. Much research has been collaborative, with colleagues and practitioners within major national projects for school improvement aimed at raising achievement in literacy and, internationally, as part of funded large-scale research projects, for example in Canada and Norway. Dr. Parr has published widely in the areas of literacy, assessment, and professional learning.

Jeong-eun Rhee is a Professor of Education, Long Island University, Post, New York. Born and raised in Seoul, Korea, she earned her bachelor's degree in Educational Psychology from Ewha Women's University. In 1992, she came to the US as an international student and received an MA in Educational Psychology from West Virginia University and a PhD in Educational Policy and Leadership from the Ohio State University. As an interdisciplinary cultural researcher and educator, her recent work focuses on developing and supporting transnational, intergenerational, and decolonial feminist knowledge projects in/through antioppressive education. She recently published *Decolonial Feminist Research: Haunting, Rememory, and Mothers*, which received an honorable mention for the 2022 Qualitative Book Award of International Congress of Qualitative Inquiry.

Fazal Rizvi is an Emeritus Professor of Global Studies in Education at the University of Melbourne, as well as at the University of Illinois at Urbana-Champaign. He is also a Visiting Professor at the Universities of Turku in Finland and Pretoria in South Africa. He has written extensively on issues of identity and culture in transnational contexts, globalization and education policy, and Australia-Asia relations. He has published widely and his book, coauthored with Bob Lingard, *Globalizing Education Policy* (Routledge, 2010), is used widely in courses around the world. A sequel to this book, *Reimagining Globalization and Education* (Routledge, 2022), has been published recently. Fazal is currently researching educational reform in Bhutan. He is a Fellow of the Australian Academy of the Social Sciences, a past Editor of the journal, *Discourse: Studies in Cultural Politics of Education*, and a past President of the Australian Association of Research in Education.

Theresa Rogers is Professor of Language and Literacy Education at the University of British Columbia. Her research interests include youth arts, media and critical literacies, adolescent literature, and teacher education in literacy. Most recently she published "Youth Activism through Critical Arts, Transmedia, and Multiliteracies" in the *Oxford Research Encyclopedia*. She is author of the book, *Youth, Critical Literacies and Civic Engagement: Arts, Media and Literacy in the lives of adolescents* (Routledge) and numerous articles in scholarly journals such as *Literacy Research: Theory, Method and Practice*, *Reading Research Quarterly*, *Pedagogies*, *Language Arts*, *Children's Literature in Education* and *Journal of Literacy Research*. See: <https://ubc.academia.edu/TheresaRogers>.

Professor Chika Sehoole is a Professor of Higher Education and the Dean of the Faculty of Education at the University of Pretoria. He obtained his PhD at the University of the Witwatersrand, Johannesburg, in December 2002. In 2003/4 he was a visiting Rockefeller postdoctoral fellow at the Centre for African Studies at the University of Illinois in Urbana Champaign. In 2005/06 he was a New Century Fulbright Fellow, again, at the same university. His research interests are in the areas of higher education policy, internationalization of higher education, higher education in Africa, and teacher education. He has served in several international research projects focusing on higher education and providing expertise from the South African and African perspectives. In 2013–2017 he served as the Chairperson of the Board of the African Network for Internationalisation of Education (ANIE). He currently serves as the chairperson of the Education Deans' Forum of South Africa. He has published a singled authored book titled "Democratising higher education policy, constraints of reform in post-apartheid South Africa" by (Routledge); three edited scholarly books on higher education and more than 40 articles in journal articles, book chapters, and popular media.

Roland Sintos Coloma is a tenured Full Professor of Teacher Education at Wayne State University in Detroit, Michigan. A scholar of history, cultural studies, and education, his research addresses critical questions of race, gender, and sexuality from transnational and intersectional perspectives. His publications include *Asian Canadian Studies Reader* (2017), *Filipinos in Canada: Disturbing Invisibility* (2012), and *Postcolonial Challenges in Education* (2009). His articles have been published in top-ranked peer-reviewed journals, including *Curriculum Inquiry*, *Discourse: Studies in the Cultural Politics of Education*, *Educational Studies*, *Educational Theory*, *History of Education Quarterly*, *International Journal of Qualitative Studies in Education*, *Paedagogica Historica*, and *Race Ethnicity and Education*. He has successfully garnered over \$2 million of external funding from federal, education, and nonprofit agencies, including the US Department of Education, National Education Association, Spencer Foundation, and Schultz Family Foundation as part of the Bill & Melinda Gates Foundation's Grand Economic Challenges. Roland has served in various university leadership roles as an assistant dean, department chair, graduate coordinator, and center codirector. He was president of the American Educational Studies Association (2018–19), editor of the *Educational Studies* journal (2014–17), and program cochair of Division G (Social Context of Education) in the American Educational Research Association (AERA). He received the 2017 Distinguished Scholar Award from the AERA Research on the Education of Asian Pacific Americans SIG and the 2015 Article of the Year Award from the AERA Queer Studies and Education SIG. In 2020, he was appointed to the Governor of Michigan's statewide Asian Pacific American Affairs Commission. Born in the Philippines and raised in California, he completed his PhD in Cultural Studies in Education and Minor in African American and African Studies from The Ohio State University in 2004.

Roger Slee is the Founding Editor of *The International Journal of Inclusive Education* and *The Journal of Disability Studies in Education*. A former Deputy Director-General of Education in Queensland, Australia, he has advised governments on inclusive education policy and practice. His published books include: *The Irregular School*; *Inclusive Education Isn't Dead, It Just Smells Funny*; and *Ethics and Inclusive Education: Disability, Schooling & Justice* (with Gordon Tait). Roger was commissioned by the UNESCO to write the scoping paper for the 2020 Global Education Monitoring Report, *Inclusion and Education*. Roger also held the Chair of Inclusive Education at the Institute of Education, London, and is now the Diamond Jubilee Professor of Disability & Inclusion in the School of Sociology & Social Policy at the University of Leeds.

Ninni Wahlström is a Professor of Education at Linnæus University, Sweden. Her current research focuses on transnational and national policy discourses and their implications for national curriculum and classroom teaching from a perspective of curriculum theory and educational philosophy. Most recent publications are "School and democratic hope: the school as a space for civic literacy" in *European Educational Research Journal* (2022) and Wahlström (Ed.) *Equity, Teaching Practice and the Curriculum*, Routledge (2022).

Lei Wang is Professor and PHD advisor of the Institute of Chemical Education, the College of Chemistry in Beijing Normal University (BNU). She is also the member of Teaching Steering Committee on Basic Education of Ministry of Education of China and the director of its branch Committee on Secondary Chemistry Education, the director assistant of Faculty of Education of BNU, vice director of the Institute of Science Education of BNU, and Chairman of the Chemistry Education Committee of the Chinese Chemical Society. She is one of the chief experts in developing the *Secondary School Chemistry Curriculum Standards* of MOE. She works as the chief editor of high school chemistry textbooks (Shandong Science and Technology Press, 2004 and 2019 editions) and junior high school chemistry project-based learning textbooks (Shanxi Education Press, 2018 edition). She achieved the first prize of the National Basic Education Teaching Achievement Award, the second prize of the National Higher Education Teaching Achievement Award, and the BAOGANG Education Outstanding Teacher Award.

Everard Weber is a retired professor. He has worked in the field of education for more than 40 years. Currently he is a research associate at the University of Johannesburg (UJ) and an academic advisor in the Future Professors Programme (FPP) at UJ. He studied African Languages and History at the University of Cape Town and Comparative and International Education at Harvard University. In South Africa he has worked at Crestway High School in Cape Town, the University of the Witwatersrand, and the University of Pretoria. A recent book is *A home away from home: a community of international and South African university students*. The FPP is a government-sponsored initiative that seeks to develop the next generation of professors and academic leaders in all disciplines, across all universities in South Africa. He is in addition presently conducting fieldwork on curriculum change in South African higher education with Professor Shireen Motala and Dr. Venise Joubert at UJ. This project is grounded in the history of southern Africa and hopes to contribute to the scholarship of postcolonialism.

Ian A.G. Wilkinson is Professor in the Department of Teaching and Learning at The Ohio State University and Honorary Professor in the School of Curriculum and Pedagogy at the University of Auckland, Aotearoa/New Zealand. He has a background in educational psychology with special interests in cognition, instruction, and research methodology as they relate to the study of literacy. He served as coauthor of the influential report, *Becoming a Nation of Readers* (National Academy of Education, 1985). He was Co-Editor of *Reading Research Quarterly* from 2006 to 2012 and was inducted into the Reading Hall of Fame in 2021. His research examines the impact of classroom discussion and dialogue on students' reading comprehension and argument literacy and the implications for professional development of teachers. Recently he coauthored books include *The Most Reasonable Answer: Helping Students Build Better Arguments Together* and *Quality Talk About Text: Discussion Practices for Talking and Thinking About Text*.

David B. Yaden, Jr., PhD, is the *Jewell M. Lewis Endowed Distinguished Professor of Literacy* in the Department of Teaching, Learning and Sociocultural Studies at the University of Arizona. Prior to his present position at the University of Arizona, he held appointments at Emory University, the University of Houston, and the University of Southern California. He served as Co-Editor of the *Journal of Literacy Research*, one of the premier research journals in the field of literacy studies, and was a Principal Investigator in the federally funded Center for the Improvement of Early Reading Achievement (CIERA) where he implemented an early literacy curriculum for linguistically diverse preschoolers in inner-city Los Angeles. He also directed a statewide consortium of researchers from Arizona's major universities in the evaluation of the state's early childhood initiative to evaluate health, developmental, and educational factors contributing to school readiness. His research interests and specializations include developmental issues in early childhood education, the acquisition of literacy and biliteracy in young emergent bilingual children, family literacy, theories of reading disability, microgenetic research design, and the application of complex adaptive systems theory to growth in reading and writing.

Volume 11: The Rise of STEM Education

Xiufeng Liu and Lei Wang

© 2023 Elsevier Ltd. All rights reserved.

Introduction

Science, Technology, Engineering, and Mathematics, or STEM, is currently a buzz word in all sectors of the society such as mass media, business, industry, government, and education in the United States and around the world. The origin of the acronym of STEM is believed to be attributed to the US National Science Foundation (NSF) that used STEM to group its program areas in education and workforce development (Hallinen, nd). Although another acronym, SMET (Science, Mathematics, Engineering, and Technology) was already in use at NSF before STEM was in common use, in 2001 the assistant director of NSF's Education and Human Resources Directorate, Judith Ramaley, suggested that STEM would be better aesthetically and conceptually (Patton, 2013). Since then, NSF has been consistently using STEM to refer to a convenient cluster of programs in its publications and budget requests to the Congress. With its inroad into public legislation and mass media, STEM workforce development with a focus on STEM's critical role for national economic development and international competitiveness became a national priority, and STEM education began to emerge as a new field of study and practice in the United States. Over the years, STEM education has become a recurring theme for education policies, workforce development, and educational research in the United States and has gradually become a world-wide movement (e.g., European Schoolnet, 2018; Office of the Chief Scientist, 2014; Center for STEM Education, 2018; Royal Academy of Engineering, 2016).

Despite its popularity and importance of STEM education, there remains no coherent conceptualization or universally agreed upon definition of STEM education (Holmlund et al., 2018). One notion accepted by many in STEM education community is the integrated nature of studies across individual disciplines of science, technology, engineering, and mathematics, given that science, technology, engineering, and mathematics are established school subjects, but interdisciplinary learning is missing. There is considerable overlap in conceptual ideas and practices between STEM education and disciplinary education of science, technology, engineering, and mathematics (Moore et al., 2020). Although STEM education emphasizes integration, STEM is not a single subject for preK-12; it does not replace individual school subjects of science, technology, engineering, and mathematics. STEM education research encompasses many areas of inquiry, such as curriculum, instruction, assessment, teacher education, educational leadership, informal education, technology integration, educational policy, career development, and relations with individual school disciplines of science, technology, engineering, and mathematics.

In education, the idea of integration is not new. Project-based learning, commonly employed in STEM teaching to promote integrated learning, has its origin in Dewey's ideas of experiential, hands-on, and student-directed learning (Maida, 2011). For Dewey, learning occurs within a social environment and knowledge is constructed through social interaction and reflection. Student learning experiences should be relevant to student everyday lives and lead to continued learning in the future (Dewey, 1938). In order for the above learning to take place, learning needs to be integrated.

The longest history of promoting integration is the integration of mathematics and science by the School Science and Mathematics Association (SSMA). SSMA was formed in 1902 with a mission to promote the integration of science and mathematics. The association's official journal, *School Science and Mathematics*, is "emphasizing research on issues, concerns, and lessons within and between the disciplines of science and mathematics in the classroom" (<https://www.ssma.org/school-science-and-mathematics-journal>). For example, *School Science and Mathematics* journal ran a feature column/department called School Science and Mathematics Integrated Lessons (SSMILes) from January 1989 all the way through the 2000s. There have been many other attempts to promote integrated learning in STEM over the past decades. In the 1970s, UNESCO initiated an international movement to promote integrated science teaching and learning in K-12 schools, with a series of publications entitled "New Trends in Integrated Science Teaching, Vols. 1-7" (Unesco, 1971, 1973, 1974, 1977, 1979). The world-wide Science-Technology-Society (STS) education movement in the 1980s and 1990s was another prominent example of integrated education (Solomon and Aikenhead, 1994). Recently, the US Next Generation Science Standards (The NGSS Lead states, 2013; NRC, 2012) promotes a strong notion of integrated science teaching and learning through a three-dimensional integration of core disciplinary ideas, science and engineering practices, and crosscutting concepts. The inclusion of engineering into science education also represents a bold vision for the future of science education in the United States. Finally, for each performance expectation, NGSS makes explicit connections to Common Core curriculum standards in which math and English language arts learning expectations are specified.

In 2014, the National Research Council published a consensus report titled "Integration in K-12 Education: Status, Prospects, and an Agenda for Research." The report presents a framework of STEM education in terms of four features: goals of integrated STEM education, outcomes of integrated STEM education, nature and scope of integrated STEM education, and implementation of integrated STEM education. In terms of goals of integrated STEM education, the following goals were identified: (a) STEM literacy, (b) 21st century competencies, (c) STEM workforce readiness, (d) interest and engagement, and (e) making connections. In terms of outcomes of integrated STEM education, the following outcomes were identified: (a) learning and achievement, 21st century competencies, (b) STEM course taken, educational persistence and graduation rates, (c) STEM related employment, (d) STEM interest, (e) Development of STEM identity, and (f) ability to make connections among STEM disciplines. In terms of nature and scope of integrated STEM education, the following aspects were identified: (a) types of STEM connections, (b) disciplinary emphasis, and (c) duration, size, and complexity of initiatives. Finally, for the implementation of integrated STEM education,

the following components were identified: (a) instructional design, (b) education supports, and (c) adjustments to the learning environment. In addition to the above features for students, the report also identified corresponding features for teachers. Specifically, goals of integrated STEM education for teachers include increased STEM content knowledge, increased pedagogical content knowledge, and changes in teaching practice. The framework provides “a vocabulary for researchers, practitioners, and others to identify, describe, and investigate specific integrated STEM initiatives in the US K-12 education system” (p. 31, NRC, 2014).

Scholarship on STEM education has been taking place since early 2000s. The *Journal of STEM Education: Innovations and Research* aims “to promote high-quality education at all levels in science, mathematics, engineering, and technology” (<https://www.jstem.org/jstem/index.php/JSTEM/about>). It emphasizes real-world case studies that focus on issues relevant and important to STEM practitioners. The *International Journal of STEM Education* was established in August 2014 (<https://stemeducationjournal.springeropen.com/>). It is a multidisciplinary journal in subject-content education that focuses on the study of teaching and learning in STEM. On the other hand, the *Journal for STEM Education Research*, launched in December 2018, “is an interdisciplinary journal in subject content education focusing on research in STEM (Science, Technology, Engineering, and Mathematics) education, which promotes the development of STEM education research as a distinct field” (<https://www.springer.com/journal/41979>). Most recently, *Disciplinary and Interdisciplinary Science Education Research* (DISER) was launched in November 2019; it promotes scholarship and best practices in education within and across science disciplines (<https://diser.springeropen.com/about>).

There have been various conceptualizations of integration (Czerniak and Johnson, 2020). There is no universally agreed definition or conceptualization of integration, and it is very difficult to derive such one. For example, for the integration of mathematics and science, a NSF-supported 3-day conference with the participation of 60 individuals representing scientists, mathematicians, science, and math educators, as well as educational psychologists and curriculum experts, was unable to reach a consensus on a definition of integrated mathematics and science (Berlin and White, 1992). Based on the conference discussion, the Berlin-White Integrated Science and Mathematics model identified six aspects that may be used to categorize various notions of integrated mathematics and science; they are (a) ways of learning, (b) ways of knowing, (c) process and thinking skills, (d) content knowledge, (e) attitudes and perceptions, and (f) teaching strategies (White, 1994).

Petrie (1992), from a philosophy of science perspective, distinguishes among disciplinary, multidisciplinary, interdisciplinary, and transdisciplinarity. He claims that interdisciplinarity cannot be understood unless we understand the concept of disciplinarity. According to him, disciplinarity is characterized as (a) a specialized knowledge, (b) unity of a common set of concepts, specialized methods, and (c) an organized group of people who study the discipline, train other practitioners, and form the social mechanism for deciding among varying truth claims within the discipline. Compared to disciplinarity, multidisciplinary is characterized as “the idea of a number of disciplines working together on a problem, an educational program, or a research study. The effect is additive rather than integrative” (p. 303). Multidisciplinary is “group work” rather than “team work.” Interdisciplinarity is characterized as “the integration of the work goes beyond the mere concatenation of disciplinary contributions” (p. 304); it is “team work.” Finally, transdisciplinarity is characterized as the integration of knowledge in meaningful ways across many disciplines. Accordingly, integration may be considered as a continuum from disciplinary to multidisciplinary to interdisciplinary to transdisciplinary (Ji et al., 2015). In this continuum, multidisciplinary is the integration in which ideas or approaches from other disciplines are drawn to solve disciplinary problems; interdisciplinary is the integration in which different disciplines form a coherent approach to solving a real-world problem while maintaining the boundaries of individual disciplines; and transdisciplinary is the integration in which problems, ideas and approaches transcend disciplines by blurring disciplinary boundaries.

Based on the above frameworks of STEM education and the conceptualization of integration, articles in this volume are organized into six sections. Section 1 includes 10 articles addressing various theoretical perspectives of STEM education. These perspectives include nature of interdisciplinary learning, characteristics of Science, Technology, Engineering, Art and Mathematics (STEAM) education, mathematics and engineering in STEM education, language, multimodalities and multiliteracies, creativity, spatial thinking, and computational thinking. Section 2 presents approaches to STEM education. It includes 16 articles on inquiry teaching, makerspace and robotics, models and modeling, problem-based learning, place-based learning, integration of socioscientific issues, play-based STEM learning, STEM schools, virtual reality, STEM curriculum development and implementation, designed-based education, technology-enhanced STEM learning, citizen science and informal science learning, and community engagement in STEM. Section 3 deals with STEM teacher education. It includes nine articles related to teacher beliefs and perceptions of STEM and STEM education, preservice- and inservice-teacher education, and scholarship of teaching for reforming university STEM teaching. Section 4 addresses the equity and inclusion in STEM Education. It includes four articles on universal design for STEM education, racial and gender equity in STEM education, and integrating indigenous knowledge in STEM education. Section 5 addresses topics on student STEM career aspirations. This section includes six articles on STEM workforce development, family influence in STEM career aspiration, student motivation, self-efficacy and career aspiration, and STEM career positioning. The final section deals with measurement and evaluation of STEM education. It includes four articles on assessment of integrated STEM learning, measurement of STEM affective learning, assessment of sensemaking, and neurocognitive and physiological measurement of STEM learning processes.

The papers in this volume follow no particular format; they are in forms of a literature review, historical account, empirical study, or summary of their own recent research; they approach a topic from diverse theoretical and methodological perspectives. In accordance with the intention of the fourth edition of the Encyclopedia to be international, this volume includes contributions from around the world to provide global conversations about the diverse conceptions, purposes, policies, and practices of STEM education. Authors are from Australia, Canada, China, Finland, Hong-Kong (China), Ireland, Israel, Sweden, and the United States. In order to reflect the latest development of STEM education, the authors were identified mainly from conference programs of the

National Association for Research in Science Teaching (NARST), a world-wide organization for improving science teaching and learning through research, American Educational Research Association (AERA), European Science Education Research Association (ESERA) from 2019 to 2021. We hope collectively the contributions provide a comprehensive introduction to STEM education world-wide.

Nature of interdisciplinary science learning

Interdisciplinary learning

The high demand of working and thinking across disciplinary boundaries in frontier research and development mandates a rethinking of STEM education (e.g., Erduran, 2020; Shen et al., 2015). Interdisciplinary learning, in a broad sense, refers to the type of learning that cuts across disciplinary boundaries (Boix Mansilla and Duraing, 2007; Klein, 1996). It can promote deeper understanding and long-term effectiveness since it enables students to integrate and apply knowledge across disciplinary boundaries (Ivanitskaya et al., 2002; McComas and Wang, 1998; Steen, 2005). An interdisciplinary learning approach can also help students make connections to the real world and prepare them for better employment in the new century (National Academies of Sciences, Engineering, and Medicine [NASEM], 2018).

Different terms have been used to describe interdisciplinary learning approaches (National Academy of Engineering [NAE] and National Research Council [NRC], 2014). An *integrated* approach stresses blending different subject matters to form a seamless whole and as a result, no clear distinction exists among the disciplines (Lederman and Niess, 1997); A *transdisciplinary* approach focuses on addressing complex problems or issues at hand without any *a priori* disciplinary lenses (Klein, 2008); A *multidisciplinary* approach emphasizes clear disciplinary boundaries and traditions when combining ideas and methods without imposing a unified framework (Drake and Burns, 2004); A *cross-disciplinary* approach refers to the range of activities that cuts across multiple disciplines, without necessarily blending in disciplinary ideas or techniques (Cross-disciplinary Learning, 2012). These interpretations of the specific terms are not necessarily universal and may have variations across contexts (NASEM, 2018).

Acknowledging the overlaps among all these terms, we choose the term *interdisciplinarity* in this article to emphasize the space where different disciplines connect and interact. We submit that individual disciplines are the building blocks for interdisciplinary work (Tripp and Shortlidge, 2020; Walshe et al., 2017; Zhang and Shen, 2015). Therefore, it matters which disciplines are involved and which disciplines are prioritized when an interdisciplinary learning approach is adopted.

Knowledge categorization and practices in interdisciplinary science learning

We consider the nature of interdisciplinary learning from two perspectives: knowledge categorization and learner practices. During interdisciplinary learning, a learner is situated in a boundary space where two or more disciplinary fields intersect. As such, interdisciplinary learning may involve different levels of and processes in disciplinary boundary crossing. Since we are focusing on interdisciplinary learning related to science (in this article, the term *science* mainly refers to the natural sciences unless otherwise noted), boundary crossing may involve different levels of knowledge categorization with respect to how science is involved: within sciences, across STEM fields, or between science and non-STEM fields.

Despite the different types of boundary crossing, what lies in the center of interdisciplinary learning is the interdisciplinary practices: what learners are actually doing in order to connect the disciplines. In this article, we adopt the framework proposed by Shen et al. (2015) in which four interrelated interdisciplinary reasoning and communication practices are essential in interdisciplinary learning:

- Translation: Map vocabularies and terms between/among disciplines in order to understand interdisciplinary topics or effectively communicate and collaborate with others from different disciplinary backgrounds.
- Transfer: Apply concepts, theories, models, tools, and methods learned from one discipline to explain phenomena and processes in another, recognizing the similar system under study.

- Integration: Connect concepts, theories, models, tools, and methods learned from different disciplines into a coherent whole to understand natural phenomena and solve complex problems.
- Transformation: Use concepts, theories, models, tools, and methods learned from one or more disciplines to physically or conceptually change or create a system or entity typically considered in another discipline or a new context.

Fig. 1 illustrates aforementioned conceptual framing of interdisciplinary science learning. The next sections are organized around the three levels of boundary crossing (i.e., within sciences, across STEM, with non-STEM). In each section, we use different examples to illuminate insights and issues related to interdisciplinary science learning while highlighting different aspects of the interdisciplinary practices (i.e., translation, transfer, integration, and transformation). Although we introduce each of the practices in different places, the reader should keep in mind that all of these practices are closely related to each other and often occur simultaneously in an interdisciplinary learning context.

Levels of boundary crossing

Connecting disciplines within the natural sciences

Making connections across disciplines in learning has been promoted within the sciences ([American Association for the Advancement of Science \[AAAS\], 2011](#); [Czerniak and Johnson, 2014](#); [NRC, 2005](#)). The report “Vision and Change in Undergraduate Biology Education” ([AAAS, 2011](#)) lays out six core competencies and disciplinary practices in biology education that also speak to the importance of interdisciplinary thinking: (1) ability to apply the process of science, (2) ability to use quantitative reasoning, (3) ability to use modeling and simulation, (4) ability to tap into the interdisciplinary nature of science, (5) ability to communicate and collaborate with other disciplines, and (6) ability to understand the relationship between science and society.

The NEXUS/Physics ([Redish et al., 2014](#)) is an exemplar project that takes an interdisciplinary approach to reform disciplinary science instruction at the undergraduate level. Addressing the challenge that many topics in physics courses have very limited relevance to students in life sciences, the project developed a physics curriculum that connects and supports biology and chemistry courses taken by life sciences students. The curriculum emphasizes interdisciplinary examples that students may see in other

Fig. 1 Boundary crossing and interdisciplinary reasoning and communication practices in interdisciplinary science learning between two disciplines A and B.

(life) science courses. The NEXUS/Physics project highlights that developing interdisciplinary competency needs to enter as a core learning objective in an interdisciplinary curriculum. Unlike other well-defined learning objectives in educational reform, often-times we do not define or operationalize what interdisciplinary competency means.

Related to operationalizing interdisciplinary learning, one challenge that prevents effective interdisciplinary learning innovations is high quality assessment specifically designed to measure interdisciplinary learning (Gao et al., 2020). Few approaches and little empirical work existed on assessing students' interdisciplinary understanding, especially at the college level. Using an essay-based approach, Tripp and Shortlidge (2020) developed the Interdisciplinary Science Rubric (IDSR) to measure undergraduate students' interdisciplinary science thinking as demonstrated in their writing. The rubric incorporated five key aspects: objective, disciplinary grounding, integration, disciplinary humility, and collaboration. The writing assignment was administered in multiple science courses and the results indicated that the rubric produced valid data to assess students' interdisciplinary thinking in sciences. Using the topic of osmosis as a testbed, Shen et al. (2014) developed an instrument to assess college students' interdisciplinary conceptual understanding in sciences. The instrument was administered to more than 1200 students using an online platform. A Rasch partial credit analysis showed that the instrument demonstrated satisfactory psychometric properties. Student performance on the assessment suggested that the growth of college students' interdisciplinary understanding was very limited compared to the growth of their understanding of the foundational, disciplinary knowledge of the topic.

Shen et al. (2014) also revealed that the issue of translation (i.e., mapping terms across disciplines) was a key barrier for many students to solve interdisciplinary problems. A follow-up study (Sung et al., 2015) showed that osmotic pressure has been defined differently in twenty well-circulated college science textbooks. This phenomenon related to interdisciplinary translation has also been documented on other concepts common across science disciplines (e.g., for the concept of energy, see Boo, 1998; Kohn et al., 2018; Redish et al., 2014; Storey, 1992). Without accurate translation, crosscutting concepts such as energy may be interpreted differently in different science disciplines, preventing effective learning (Sung, 2012).

Likewise, educators who are engaged in designing interdisciplinary curriculum materials need to have or develop proficiency in interdisciplinary translation. The projects reported in Redish et al. (2014) and Shen et al. (2015) both illustrated the importance of having an interdisciplinary team who is willing to engage in an open dialog about the core objectives and different perspectives in an interdisciplinary educational reform. Acknowledging the different disciplinary viewpoints is a good starting point, as Redish et al. (2014) rightly pointed out:

Biology faculty and physics faculty tend to have dramatically different views about the nature and structure of the knowledge that is appropriate to teach in introductory classes. Biology students tend to have difficulty and may even actively resist seeing the value of physics and mathematics in their learning of biology.

Shen et al. (2015) described a similar situation in which a group of faculty members and graduate students from different science disciplines (physics, chemistry, biology, and veterinary medicine) struggled for a long time just to understand each other. The team was working together to create interdisciplinary assessment item that can be used in their science courses but were distracted by and stuck with terminology translation. They found that inscribing group ideas with tools such as concept map would help team members better communicate with each other.

While generally applicable in almost all different boundary-crossing scenarios, the issue of translation is often overlooked within the natural sciences—people assume that all the scientific terms have been operationalized and well defined across disciplines. In a well-designed interdisciplinary science learning environment, students need to acquire sufficient vocabulary to converse on a topic that involves multiple domains, the ability to distinguish and translate terminologies between fields, and sensitivity regarding distinctive interpretations with certain terms (Nikitina, 2005). With disciplinary knowledge becoming so narrowly specialized nowadays, it is also critical for instructors to develop the ability to effectively present and communicate knowledge among student audiences who do not speak the same scientific language.

Connecting science across STEM fields

There have been many different ways of connecting math with science (Czerniak and Johnson, 2014; Thibaut et al., 2018) or connecting fields within STEM (Kelley and Knowles, 2016). One aspect to consider is the unit of integration, e.g., in-course, within-curriculum, and co-curricular (NASEM, 2018). Here we mainly consider two modes (hierarchical and flat) that in a way are aligned with two of the IRC processes (transfer and integration). In the hierarchical (transfer) mode, one discipline serves as the knowledge base for learning the other. In other words, one discipline serves as the means and the other the ends. In comparison, a flat (or integration) mode places different disciplines at the same level with more or less equal treatment.

Hierarchical mode

The hierarchical mode is the primary mode in most college science or engineering courses when math is concerned, considering that students are expected to apply math knowledge to understand science concepts or solve engineering problems. It is often said that mathematics is the language for science (Gamow, 1988; Redish and Kuo, 2015; Wigner, 1960). Research shows, however, a common

topic may be treated very differently in a math and a science class (e.g., measurement, [Shen and Jackson, 2013](#)). Usually, math courses are taught independent of science courses at the college level, making integration much more challenging ([Gross, 2000](#); [Feser et al., 2013](#)).

Many advanced science classes require certain math courses as prerequisite or deal with certain math concepts just-in-time, as evident in NEXUS/Physics ([Redish et al., 2014](#)). [Feser et al. \(2013\)](#) described two specific approaches to integrating quantitative reasoning for biology learning: the MathBench Biology Modules at the University of Maryland rendered through an interactive web-based platform that integrates essential quantitative concepts in biology learning, and a textbook developed at Davidson College that emphasizes learning biology through the analysis and interpretation of quantitative data. In another example, [Walshe et al. \(2017\)](#) described a curriculum in which mathematics concepts were included mainly for serving inquiry science learning.

Whereas sciences may be used as an application field for math, engineering is often used as an application field for both math and science. For example, [Xie et al. \(2018\)](#) piloted the Solarize Your Home Project module with high school students in the north-east of US. In the module, students built computer models of their own houses and installed solar panels on the roof for household power supply with the aid of Energy 3D, a software that can inform engineering design with scientific simulations (e.g., visualizing the sun path, showing heat transfer through walls and windows, displaying daily or annual energy consumption curve of the house). Related science (e.g., heat transfer, energy conservation) and math knowledge (e.g., angles, balancing equations) were desired for students to create a model of an energy-efficient house.

Although in most cases, interdisciplinary transfer occurs in the direction from a more abstract or general domain to a more concrete or specific domain (e.g., from math to science), the direction of transfer could also go backwards. For instance, engineering design has been used to help students learn math or science concepts ([Becker and Park, 2011](#); [Guzey et al., 2014](#); [Xie et al., 2018](#); [Zheng et al., 2020](#)). Science and engineering have also been integrated for learning computational thinking. Including both formal and informal learning settings, [Yin et al. \(2020\)](#) reported a series of maker activities that were developed to help secondary-school students improve computational thinking dispositions and skills while working on physics and engineering activities (e.g., designing and making e-textiles by sewing electrical circuits with tiny LED lights onto clothes).

Transfer has been regarded as an important goal for learning in general. Even within individual disciplines students are expected to constantly transfer what they have learned from one situation to another, such as, from classrooms to out-of-school settings (e.g., [Bransford and Schwartz, 1999](#); [Chin and Brown, 2000](#); [Engle, 2006](#)). Successful transfer fosters deep learning by enabling students to enact the knowledge acquired previously. Interdisciplinary transfer, therefore, refers to the process whereby students apply models, concepts, and methods learned from one disciplinary context in order to understand phenomena or solve problems in another disciplinary context ([Kaminske et al., 2020](#)). In successful interdisciplinary transfer, learners should be able to recognize the core structure of the system or knowledge under study; they should be able to map out the parallel elements or corresponding parts along with their connections within the two disciplinary contexts.

Flat mode

Accompanied with the STEM movement ([Erduran, 2020](#)), many integrated STEM curricula are developed with the flat mode in mind: different disciplinary components are blended into a coherent whole ([Kelley and Knowles, 2016](#); [NAE and NRC, 2014](#)). [Gentile et al. \(2012\)](#) described the development of an intensive STEM course, Integrated Quantitative Science (IQS), offered to first-year college students that constituted half of their study schedule. The course was developed to help undergraduate students learn important concepts in and make connections among biology, chemistry, computer science, mathematics, and physics. While the study found promising results in terms of students' conceptual gains and perceptions toward interdisciplinary learning, the study also described challenges on how to balance and sequence the offering of different subject matters for first-year students.

At the precollege level, [Dierdorp et al. \(2014\)](#) described an interdisciplinary unit developed to help senior high school students build meaningful connections among natural science, mathematics, and statistics through professional practices. Their work highlighted an attempt to identify the different kinds of connections made by students, including math-science connection, that students exhibit when learning interdisciplinary topics. Their results indicated that integrating professional practices with science, mathematics, and statistics could help students build more connections among these disciplines. [Ntemngwa and Oliver \(2018\)](#) reported an integrated STEM curriculum for middle school classrooms that gave about equal attention to science, technology, and engineering. Adopting a project-based instructional approach, the students learned engineering by designing and building robots with the Lego Mindstorms robotics kits. Having robots ready, students then programmed them to fulfill assigned tasks. During the process, they needed to understand the science knowledge that was embedded as context in each activity. While teachers believed that their students improved in all three areas after the activities, they felt it was challenging for themselves to learn to construct and program robots, to select appropriate robotics activities in line with science contents, to take the role of facilitator during the activities, and to assess students' learning in the integrated STEM class. They also reported insufficient amount of time for this innovative curriculum.

Even documents of educational standards support interdisciplinary integration. For instance, the US Next Generation of Science Standards ([NGSS Lead States, 2013](#)) framed engineering and science practices as equally important in K-12 education. The standards listed eight core science and engineering practices:

- Asking questions (for science) and defining problems (for engineering)
- Developing and using models
- Planning and carrying out investigations

- Analyzing and interpreting data
- Using mathematics and computational thinking
- Constructing explanations (for science) and designing solutions (for engineering)
- Engaging in argument from evidence
- Obtaining, evaluating, and communicating information

As one can see from the list, six of the practices are presented as common across science and engineering, and two of the practices have differentiated treatment (the first one and the sixth one). These common and differentiated integration treatments provide concrete directions for connecting science with engineering in K-12 classrooms.

Similar to transfer, integration is often promoted as an important practice for both disciplinary and interdisciplinary learning. Acknowledging the fact that students bring with them a wide range of ideas, knowledge integration has been promoted as a main objective for learning within sciences (Linn, 2006; Shen and Linn, 2011). The framework emphasizes enhancing students' abilities in establishing various types of connections among scientific ideas. This framework can be expanded to interdisciplinary learning with special attention paid to integration across disciplinary boundaries (Shen et al., 2014). In interdisciplinary integration, students need to explain phenomena by incorporating multiple discipline-based concepts and tools. More importantly, they need to be more conscious about the discrepancies and mismatches in knowledge across disciplinary boundaries.

Connecting science with non-STEM fields

Interdisciplinary science learning has also been attempted in connecting science with non-STEM fields. In response to the question whether or not the disciplinary structure of higher education adequately prepares students for the 21st century, the [US National Academies of Sciences, Engineering, and Medicine \(2018\)](#) formed a committee to examine existing evidence on the effectiveness of "educational programs that mutually integrate learning experiences in the humanities and arts with science, technology, engineering, mathematics, and medicine (STEMM)" (p. 2). The committee collected a list of 218 programs and courses that integrate the humanities, arts, and STEMM fields (for the list, search "Compendium of Programs and Courses That Integrate the Humanities, Arts, and STEMM"). The committee examined a wide range of evidence and concluded that some integrative approaches are associated with positive learning outcomes, including increased critical thinking and higher-order thinking, problem solving, teamwork and communication skills, ethical decision making, and enjoyment of learning. Many of these skills are aligned with what modern employers are looking for.

Integrating science with non-STEM fields can stimulate students' motivation (Gao et al., 2020; Richardson et al., 2020). For instance, weaving arts in science learning can promote learners' inspirations and interests (Copeland et al., 2018). Burg et al. (2016) developed a curriculum in which math, science, and computer science were integrated with music and digital sound production. For another example, Bopegedera (2005) described a program in which students participated in both art workshops and science labs in order to apply scientific understanding to create artistic products. In these programs, students get to experience new learning activities that cut across disciplinary boundaries, which may engage and motivate students to learn, especially those who are fed up with rote learning.

Integrating science with non-STEM fields can promote new ways of expressing and disseminating scientific knowledge. An interesting event to consider is the Dance Your Ph.D. contest, organized by the esteemed Science Magazine. Contestants have to submit a dance performance to present their dissertation ideas. For example, the 2019 Dance Your Ph.D. winner in the physics category was about singleton electrons wandering through superconducting material (Bohannon, 2019). The 2020 winner of the overall prize was taken by Groneberg, who explored "how the motions of groups of zebrafish larvae affected each individual animal's brain development and behavior, teasing out the impact by raising some larvae in isolation and documenting any differences" (Travis, 2020). The goal of the contest was not necessarily to create new knowledge but to transform and communicate knowledge generated in Ph.D. dissertations in a new, artistic form.

Many modern societal problems, especially social scientific issues such as a global pandemic or climate change, require expertise from the STEMM fields as well as arts and humanities (NASEM, 2018). In education, this is often framed as a problem-based learning in which learning is driven by complex problems (e.g., Hmelo-Silver, 2004). For example, Braßler (2016) described an interdisciplinary problem-based course at Hamburg University to teach sustainability in which learning were driven by highly complex problems such as corruption, health inequality, and social inequity. Research has shown that disciplinary perspectives and experiences, positive or negative, play an important role in interdisciplinary problem solving in terms of conceptualizations, strategies, and attitudes (Slominski et al., 2020; Zhang and Shen, 2015). Another good example is the MIT's Terrascope program (<https://terrascope.mit.edu/overview/>). The program engages first-year college students in working on solutions addressing global problems such as clean water shortage and natural disaster with interdisciplinary research and a supportive community.

Another form of learning approach often overlapping with interdisciplinary learning is project-based learning (e.g., Solomon, 2003). In project-based learning, student learning is driven by relatively long-term projects. The STEM and Digital Literacies with Adolescents (STEM+L) project (Smith and Shen, 2017) is a good example. The STEM+L project investigated science fiction as an effective mechanism to immerse adolescents from diverse cultural backgrounds in STEM content, digital literacies, and socio-scientific issues (Ran et al., 2020). The participating students worked in small groups to design and produce multimodal science fiction in both formal and informal learning contexts. Participants chose discipline-specific roles (e.g., scientist, designer, writer) and used an array of digital tools to accomplish their collaborative projects. Culminating

activities included student presentations at a local science fiction film festival. The research revealed the distinctive patterns and trajectories about how adolescents with different backgrounds collaborated, learned, and developed distinctive disciplinary or interdisciplinary identities during the process (Jiang et al., 2019a,b). The theme of science fiction has also been explored for the interdisciplinary learning at the college level. For example, Copeland et al. (2018) reported a course, *The Science in Science Fiction*, designed by faculty members from Biology, Physics, and English departments. In the course, students read and discussed a range of science fiction texts and also conducted cross-disciplinary, collaborative research on topics of their choice. Overall, the students reported very positively about the course experience, but also acknowledged that the collaborative research across disciplines was especially challenging.

The aforementioned examples illustrate that transformation is often presented as the goal of a typical project that blends in science with non-STEM fields—generating new knowledge and/or making new products (Carlile, 2004; Carlile and Rebentisch, 2003). Intuitively, transformation is naturally linked with creation and production, suggesting an important role for arts in this endeavor. Authenticity is also a critically important consideration when including transformation in an interdisciplinary learning environment. Transformation not only involves the change in a system or entity in a different discipline in a theoretically sound way, but also results in products and solutions that are of practical importance to a local or larger audience. Having an authentic audience, which has been included as an important design feature for many of the aforementioned examples, may provide students with a sense of making real impact.

Promoting interdisciplinary science learning

Strategies for facilitating interdisciplinary science learning

The above sections presented examples of educational programs or curricula designed to facilitate interdisciplinary science learning in terms of different levels of boundary crossing. While these programs may have different goals and objectives in mind, they all promote the type of learning that requires students to connect and apply knowledge across disciplinary boundaries.

The literature suggests a wide range of pedagogies in support of an interdisciplinary science learning environment. These include generic constructivist pedagogies that encourage integrated learning (e.g., Knowledge Integration; Linn, 2006) or community building (e.g., Knowledge Building; Scardamalia and Bereiter, 2006), and pedagogies such as project-based or problem-based learning approaches that have inherent affordances to support interdisciplinary learning (Brassler and Dettmers, 2017; Lou et al., 2011, 2017).

New pedagogies and technologies should be explored and developed to better facilitate interdisciplinary science learning in the ever-changing world. For example, discipline-specific role-taking has been promoted as a strategy to facilitate interdisciplinary learning (Smith and Shen, 2017). In this strategy, students may choose and take on different roles (e.g., scientist, writer, artist, designer) when working on a collaborative project. These roles could be provided by instructor, or proposed by students themselves. They could also create hybrid roles (e.g., scientist/designer), which in a way help developing individuals' interdisciplinary identity. While working on their collaborative, interdisciplinary projects, students may see how their own interests and expertise can be connected with different areas and future careers. Research shows that this strategy may help students form core disciplinary identities (i.e., developing individual expertise and interests related to the roles they take), while gaining knowledge and expanding perspectives in other disciplines (Jiang et al., 2020).

From the technological perspective, tools should also be developed to mediate the interdisciplinary collaboration processes. For example, the iKOS platform, a web-based knowledge organization platform, has been developed to facilitate multimodal composition that is suited for interdisciplinary collaborative learning (Namdar and Shen, 2018; Shen et al., 2020). It supports different modes of knowledge representation. In addition to the distinctive knowledge entry modes, iKOS affords the creation and sharing of interactive flipbooks. This feature allows students to integrate content knowledge with multimodal writing and publish their products to the public, reaching a wider audience.

Practices in interdisciplinary science learning

Despite the various pedagogies and technologies, research on what students are actually doing when learning in an interdisciplinary context is limited. We presented the framework that includes four interrelated practices, namely, translation, integration, transfer, and transformation.

Translation is a critical, but often overlooked aspect in interdisciplinary science learning. Research shows that not only students need to develop a vocabulary base that connects different disciplinary fields, instructors or curriculum designers from different disciplinary backgrounds also need to engage in a collaborative dialog on how to develop and sustain an interdisciplinary learning program (Gentile et al., 2012; Redish et al., 2014). Developing a “disciplinary humility mindset” (Tripp and Shortlidge, 2020) with which one acknowledges and respects disciplinary differences, including their languages, is an important part of interdisciplinary learning for both students and instructors (Redish and Cooke, 2013; Slominski et al., 2020).

Integration and transfer may be construed as the two complementary practices that match the flat and the hierarchical modes in interdisciplinary science or integrated STEM learning. The flat mode refers to an interdisciplinary learning environment where different disciplinary topics and practices are juxtaposed at the same level. In this mode, integrating different disciplinary knowledge and methods to form a coherent whole is stressed. The hierarchical mode refers to an environment where one discipline serves as the base and the other as the application field. In this mode, transferring knowledge and models from one context to another needs to

happen across disciplinary boundaries. While they may occur in different settings, both the integration and transfer practices are essential in developing an interdisciplinary habit of mind.

Transformation refers to the practice when intentional changes are made in interdisciplinary learning settings. Programs that connect science learning with arts or humanities often have this practice built in their learning tasks (e.g., solving practical problems, designing new products, making artifacts for exhibit). Transformation often requires the execution of other interdisciplinary practices, as one has to be able to integrate, transfer, and translate an old system in order to transform it to a new one in a meaningful way.

These interdisciplinary practices should not be taken as purely cognitive—they also involve social processes. It matters not only how individual learners exercise these practices, but also how they interact and communicate with others in interdisciplinary learning settings. We believe the framework may provide guidance on how to better facilitate students' interdisciplinary learning.

Challenges for creating and sustaining interdisciplinary science learning

While many programs have shown promising results, the literature also indicates that interdisciplinary science learning faces many challenges. One challenge is theoretical: there is a lack of shared understanding on what interdisciplinary science learning means (Boix Mansilla and Duraising, 2007; NAE and NRC, 2014). This has practical implications in how to present learning objectives to students (Sana et al., 2020).

A closely related challenge is developing valid and reliable assessments that target interdisciplinary (science) learning (Shen et al., 2014; Tripp and Shortlidge, 2020). Reviewing how assessment was done in empirical studies in interdisciplinary STEM education, Gao et al. (2020) proposed a two-dimensional framework that includes nature of discipline (does the assessment target monodisciplinary, interdisciplinary, or transdisciplinary?) and objectives of learning (does the assessment target knowledge, skills, practices, or affective measures?). Gao et al.'s (2020) review showed that most assessments focused on monodisciplinary knowledge, monodisciplinary affective domains, and transdisciplinary affective domains.

Another constraint lies in the disciplinary structure of many institutions or organizations where learning occurs. There is a dilemma in terms of when to nurture interdisciplinary learning. On the one hand, if interdisciplinary learning needs to be built upon disciplinary foundations, we would assume interdisciplinary science learning should occur at a higher-grade level (say, secondary or post-secondary) when students have developed a substantial disciplinary knowledge base. On the other hand, the higher level the schooling goes, the more specified a course of study would be—implying more challenges and barriers for interdisciplinary science learning. For example, departmentalized structure in higher education is often difficult to penetrate.

Related to infrastructure, yet another challenge is related to the teachers or instructors who can deliver effective interdisciplinary science instruction. To implement an interdisciplinary learning approach, teachers need to have some basic level of knowledge of the disciplines involved. This has been a big hurdle for individual teachers to implement interdisciplinary curricula (e.g., Ntemngwa and Oliver, 2018). For a team approach, interdisciplinary learning implies a significant investment for team building as well as for each team member to get familiar with topics outside of his/her expertise (Gentile et al., 2012).

Conclusion and recommendation

We have described different examples that include interdisciplinary science learning in different boundary-crossing scenarios: within sciences, across STEM, and with non-STEM fields. These examples touch upon different aspects of interdisciplinary practices, including integration, translation, transfer, and transformation. In reviewing the literature, we submit that more empirical studies are still needed to design and test the effectiveness of the best strategies and tools to engender and assess these interdisciplinary learning practices in specific domains. In response to the challenges, we encourage more and deeper theoretical discussion on what interdisciplinary science learning means. We call for more empirical research on operationalizing and assessing interdisciplinary learning that goes beyond self-report. In order to successfully design and sustain an interdisciplinary science learning program or environment, stakeholders need to have an open and enduring discussion on setting the goals and objectives explicitly related to interdisciplinary learning. Acknowledging that it is often a long-term and challenging process, we recommend innovative ways for stakeholders to create platforms, harness materials, or seek resources in support of interdisciplinary collaboration.

STEM and arts

An ancient account relates the story that Pythagoras, the mythical forefather of Greek mathematics, was preoccupied with finding a way to quantify the perception of sound, in a similar way that a scale can quantify weight, when he walked past a blacksmith's shop and heard consonant sounds (octaves, fifths, and fourth musical intervals). Excitedly, he ran into the shop and started experimenting with the sounds the blacksmiths were making, striking metal rods with varied forces, striking on different types of metal rods, and with hammers of various weights. This experience led him to carry out a series of experiments making sounds with pipes of different lengths, cups filled with different amounts of water, and strings with different lengths and tensions, thus relating the size of the vibrating objects with their frequency, and establishing the mathematical and physical underpinnings of harmonic chords and musical scales (Fig. 1).

Although not historically accurate, this tale highlights the role of science and math in understanding human sensory perception in relation to music, and the role of music in inspiring and providing a language for physics and mathematics. Throughout history, music remained an object and an inspiration for scientific research, a link that was expressed in classic education in the quadrivium, the basis of philosophical education, put forth by Plato and used through the middle ages, comprised of Arithmetic, Geometry, Music, and Astronomy (Pesic, 2014).

Perhaps the best-known personality at the intersection of art and STEM is Leonardo da Vinci. Even though he is often conceived as a polymath with diverging interests, for da Vinci art and STEM were not independent endeavors, as one of the main goals of renaissance art was creating an illusion of reality (Isaacson, 2017). This involved, for example, the use of math to create the illusion of depth through perspective drawing, understanding how objects can be modeled in three dimensions by decomposing them into simple geometrical forms, understanding how light and color are reflected on those forms and filtered through the atmosphere, understanding anatomy, and experimenting with new materials such as pigments and oils to create vivid colors.

These examples highlight that for the renaissance STEAM professionals, creating the illusion of nature involved a deep understanding of nature. And similarly, representing nature is a prerequisite for understanding it, as is also shown in da Vinci's anatomical

Fig. 1 Pythagoras researching the physical and mathematical underpinnings of musical harmony. From Franciscus Gaffurius' *Theoria Musicae* (1492).

drawings, Bouguereau's studies of clouds, and countless other illustrators whose work was fundamental for the development of the biological sciences (The Art of Innovation, BBC, See relevant websites).

It is helpful to understand the historical connections between the arts and STEM in order to see the contemporary connections and appreciate the technological aspects of art products of the past and the artistic aspects of technological products of the present. As technology evolves, what we consider "technological" changes over time. If, as computer-pioneer Alan Kay said, "technology is anything invented after you were born," it is easy for contemporary culture to overlook the technological value in the works of da Vinci and others and in the techniques described above. As a counterpart, it is sometimes easy to overlook the artistic value of technological consumer products that are integral to our culture, relegating the idea of *Art* to traditional forms found in museums, concert halls, and academic activities. The development of video games, for example, continues the renaissance's obsession with recreating reality, incorporating its technological advances, and adding newer technologies such as artificial intelligence, physics engines, and haptic interfaces to create a more immersive and flexible environment. Similarly, the Pythagorean inquiry on the nature of sound and music is extended to include the development of electronic techniques for creating music, such as the modular synthesizer (if the reader is old enough to call it technology), the development of software for sound production and editing, and the use of artificial intelligence and signal processing for autotuning the human voice (A History of Electronic Music, see relevant websites). These examples indicate that by taking a perspective that goes beyond the narrow conceptions of Art and Science typically taught in schools, the connections between STEM and the arts are easier to find than to miss.

History and meaning of STEAM education

The acronym SMET, standing for Science, Mathematics, Engineering, and Technology, was first used by the United States' National Science Foundation in the nineties and was soon scrambled into STEM to avoid vulgar connotations (Breiner et al., 2012). STEM originally designated the four field areas, without an associated educational philosophy, but with an emphasis on training and recruiting a workforce to compete in the international arena. This conception of STEM as a grouping of fields is still used frequently, particularly in policy discussions. Over time, many in the education community came to associate it with integrative project-based and inquiry learning, as is typically experienced by STEM professionals (Breiner et al., 2012), who need to bridge disciplines to solve problems. The term gained popularity in the 2000s and led to the opening of STEM schools, the designation of specialized district administrators, and professional development programs.

The first written reference to STEAM was putatively (Mejias et al., 2021) introduced by Yakman (Yakman, 2008) as an idea for greater integration of STEM and the arts, although the idea of integrating arts and STEM fields was not new (Robinson, 2013). As the recognition of the need for integration and the acronym gained popularity, many of the STEM programs added the connections to the arts and became STEAM.

The US government has promoted STEAM education through funding and conferences (Harrell and Harrell, 2010), and the US' House of Representatives released a resolution for "adding art and design to federal programs that target [STEM]" with the goal of encouraging innovation and economic growth (Langevin, 2015).

Goals of STEAM

Enough of the STEM and STEAM literature is devoted to defining, redefining, criticizing, and disentangling the meaning of the term (Breiner et al., 2012; Colucci-Gray et al., 2019; Mejias et al., 2021). We do not intend to add to that discussion but to state that the definition of STEAM varies with the stakeholder, with a general conception of project-based learning integrating the STEM fields and the arts. It should be noted that, in practice, the arts are frequently not included, for example, many self-proclaimed STEAM programs are robotic challenges (Colucci-Gray et al., 2017). The fact that experiences as such are categorized as STEAM perhaps reflects the fact that STEAM programs inherit STEM values, and that many can see the aesthetic and artistic value in the engineering processes (Harrell and Harrell, 2010). Since a large part of society's interest in STEAM is its relationship to the arts, and since this is a chapter about STEAM in a volume about STEM, here we emphasize the importance of the arts.

Just as STEAM means something different for different people, the goals for adopting STEAM education are varied, with the common assumption that children find the art-making process engaging and personally relevant. Of particular importance for their role in establishing educational policy is the view of policymakers, represented among others by the US house of representatives, whose resolution referenced above stated that:

- 1) Innovative practices of art and design play an essential role in improving Science, Technology, Engineering, and Mathematics (STEM) education and advancing STEM research.
- 2) Art and design provide real solutions for our everyday lives, distinguish United States' products in a global marketplace, and create opportunity for economic growth.
- 3) Artists and designers can effectively communicate complex data and scientific information to multiple stakeholders and broad audiences.
- 4) The tools and methods of design offer new models for creative problem solving and interdisciplinary partnerships in a changing world.

- 5) Artists and designers are playing an integral role in the development of modern technology and manufacturing.
- 6) Adding art and design to Federal STEM programs has the potential for recruiting into STEM fields children from underrepresented ethnic and economic backgrounds.

Some of these US House's statements parallel scholars' assertions that the inclusion of the arts helps develop "creativity, problem-solving skills, exploration of uncertainty, ambiguity, and fuzziness" (Colucci-Gray et al., 2017). The idea that inclusion of the arts can *infuse* STEM practice with those values will be surprising for STEM professionals, who know the importance of creativity in STEM practice, and perhaps reflects the general conception of STEM as uncreative, developed over years of engaging with science through uncreative schooling practices. Furthermore, there is no clear evidence that the creativity exercised through art practices transfers into STEM practices (Perignat and Katz-Buonincontro, 2019). It is important to note, however, that participating in a STEAM activity gives children the opportunity to *exercise* their creativity through the creation of art artifacts, with which they are often very engaged. An opportunity that they would not have otherwise.

The US House's resolution, as well as some scholarly work, indicates that STEAM is a way to engage underrepresented students in STEM fields, although the mechanism is not usually articulated. Because of the cultural relevance of the arts, and the personal relevance in terms of student interest, arts integration can achieve several dimensions that are useful in promoting equity and diversity in STEM education: They approach learning as a cultural accomplishment, allowing for science understanding to grow out of the students' lived experiences. They relate youth discourses to scientific discourses, allowing children to express their understanding in their own language. They build on prior interest and identity, as they relate to the artistic practices, tastes, and identities that the children bring. They leverage the students' cultural funds of knowledge, as they relate to the art-making practices of their communities. They make the diversity visible, highlighting the artistic (and technological) accomplishments of creators from diverse cultures and backgrounds. And they value multiple forms of expression, allowing the children's knowledge to be assessed not by standardized exams but by the creative process and the artistic artifacts that they produce (National Research Council, 2012).

Although scholarly work generally does not report on the effectiveness of art integration programs to engage underrepresented children in STEM (Colucci-Gray et al., 2017; Mejias et al., 2021; Perignat and Katz-Buonincontro, 2019), some evidence supports this claim. An example is these authors' educational program connecting music with the physics of sound and waves (Minces et al., 2021), applied with low-income and underrepresented (Latinx) eighth-grade children in a US school near the Mexican border. In this experience, children used computers to visualize and edit sound, carried out physical hands-on explorations of vibrating objects, and used their knowledge to create musical instruments. Participating in the program significantly increased the children's perception of themselves as scientists and their intention to pursue science careers, and it greatly increased their engagement with their science class.

Because the arts are manifested as projects or artistic investigations, they are naturally fit for STEM education's project-based ethos. In the example above, when children use a sound editor to create a sound composition they are making an art piece. In the process, they are visualizing the sound's waveform, which is the physical representation of sound, they are applying signal processing transformations to that waveform (for example changing the sound's speed), they are connecting those transformations to human perception (for example noticing that waveforms that evolve faster are perceived as having a higher pitch), and they are observing that superimposing sounds is equivalent to superimposing waveforms. Furthermore, children are beginning to acquire skills that are immediately useful outside of school, and that are connected to the world of work, including sound engineering but also any field that requires recording and manipulating signals. In our program, these connections are highlighted by a series of mini-documentaries profiling young underrepresented people in fields related to sound and waves. Another notable example of the power of music integration for engaging underrepresented students in STEM fields is the popular Earsketch programming platform, in which children use computing to create electronic music (Freeman et al., 2014). In these types of experiences, the arts and STEM are intertwined, as the art form is inherently technological, and participating gives children agency not only as artists but as STEM creators. These types of experiences can be qualified as *Thickly Authentic STEAM* experiences, defined as having a) personally meaningful learning experiences; b) learning that relates to the world outside of the learning context; c) learning that encourages thinking within a particular discipline (for example sound production); and d) allowing for assessment that reflects the learning process (Freeman et al., 2014; Lee and Butler, 2003; Shaffer and Resnick, 1999).

In contrast with artistic STEM projects, some experiences reported as STEAM involve art projects about STEM fields (Mejias et al., 2021), an example being interpretative dancing about planetary motion (Glinkowski and Bamford, 2009). The latter kind of experiences put arts as subservient to STEM (Robinson, 2013). It is reported that the vast majority of arts integration reports follow this subservient model (Bamford, 2006; Robinson, 2013). A problem with these subservient experiences is that they do not position the children as curious and creative participants in STEM/STEAM practices, reinforcing the popular idea that science is an established body of knowledge guarded by "others", and children's creative practices associated with science can only be making art about it. The subservient model, however, is not without advantages. It is possible that the subservient model might serve the STEAM goal of effectively communicating scientific data, although there is no guarantee that children have a deep understanding of what they are doing art about (Colucci-Gray et al., 2017), and there is no evidence that these types of experiences actually improve science communication. Another advantage is that participating in a subservient art experience might be better than the alternative, for example, dancing the planetary motion might be better than learning about it by sitting down and staring at a whiteboard. Subservient art might also offer mnemonic advantages and bring art and movement to a school day that lacks them otherwise, particularly in low-income schools (Bequette and Bequette, 2012).

The US House resolution recognizes a goal in STEAM education that is generally overlooked in scholarly articles, which is adding the value of art and design in the development of consumer products. This is better exemplified by the carefully designed consumer products of Apple –see Steve Jobs’s Stanford commencement speech for an account of the influence of art in the development of Apple products (Jobs, 2005)– which is currently the most valued company in the world, and it can be argued that Facebook and Microsoft, two of the other technology giants, owe their success not to cutting edge technologies but to their innovations in design. The goal of adding value is notable in that it sees STEAM not merely as a conduit to better or more STEM, but as worthy in itself and integral to the economy.

Given the goals typically assigned to STEAM education, it is surprising that evaluations of STEAM programs generally focus on the children’s acquisition of domain knowledge (and without control groups that would allow an understanding of STEAM’s differential contribution). The focus on domain knowledge treats STEAM as a pedagogy, in the sense of “a method for teaching something”. The goals above, however, reveal it not so much as a pedagogy, but as a policy regarding what should be taught, why, and for whom, a reflection on what education is for.

STEAM’s reach and barriers

Published reports of STEAM experiences have a large bias toward elementary school or after-school programs (Colucci-Gray et al., 2017). Published reports, however, are created within the scholar community, and are not representative of more popular STEAM practices on the ground. To understand its real reach, we carried out informal interviews with leaders in our local, and very active (Wired Magazine, 2019), STEAM ecosystem (see acknowledgments), an approach similar to Colucci-Gray et al. (2017). These leaders have created curricula, fairs, and professional development opportunities reaching more than a million students. Although there are no precise statistics, they agree that STEM and STEAM experiences decline in middle school and high school, and are more prevalent in out-of-school environments. Through our interviews and personal experience developing a popular music integration program, we have identified several barriers to implementation, which become more prominent in higher grade in-school contexts. Some of these barriers coincide with the findings of a working group of policy experts led by the *Education Commission of the States* and the *Arts Education Partnership of the US* (Dell’Erba, 2019).

(1) Siloing: Early grades are guided by one non-specialized teacher, which makes it easier for them to apply integrative subjects. As grades increase, so does teacher specialization and subject matter siloing. In such a context, teachers need to collaborate if they are to apply integrative experiences while fulfilling the standards. This approach is taken in the well-known High Tech High School System (Wagner and Dintersmith, 2015), but teacher collaboration is much harder to implement in public schools with large class sizes and overburdened teachers. Out-of-school programs, as early grades, are typically not siloed into academic subjects, which explains their prevalence in STEAM programs. (2) Curricular pressure: Teachers are often pressed to teach a rigid curriculum or a set of standards that might not be possible to align with STEAM experiences (Dell’Erba, 2019). Whereas this is true for all grades, it is particularly influential in higher grades, where curricular topics become more microscopic and abstract. For example, it is straightforward to create an engaging STEAM activity around the first grade US standard *connecting sound and vibrations*, because the standard reflects a phenomenon that children encounter regularly, for example when they stand next to a bass speaker or drum, and because it can be directly linked with the creation of musical instruments. In contrast, we have not been able to create a personally meaningful activity linked to the middle school standard addressing *wavelength*, because wavelengths cannot be felt, are hard to visualize, and are not relatable to the children’s everyday experiences. (3) Teacher preparation: an important barrier across grades is teacher preparation (Dell’Erba, 2019). This does not only involve teaching teachers how to implement specific STEAM experiences, but also requires changing rigid teaching practices that are over-reliant on memorization and testing as a way to measure the children’s performance. (4) Teacher time commitments: teachers are often overburdened, serving several classes with more than 30 students. The time commitment and the stress of classroom management leave them little time and energy for preparation, collaboration, and carrying out the type of personalized work that supervising STEAM student creations might require (Dell’Erba, 2019). (5) Research focus: because published reports of STEAM experiences are created within the scholar community, they typically involve the participation of highly trained professionals and subject domain experts, and often involve small groups of highly motivated students participating in out-of-school programs. This is problematic because the resources thus created are hard to extrapolate to less motivated students, less well-prepared facilitators, and harder curricular constraints.

STEAM is an attempt to bring to the classroom an integration of meaningful personal interests, project-based learning, performance evaluations, communication, and collaboration. These values run counter to the structure of the educational system, which is siloed, individualistic, test-oriented, understaffed, and focused on subject domain standards that children might not find a personal connection with. In this context, two strategic questions arise: (1) How can the scholar community improve the children’s educational experience given the current systemic constraints?; and (2) What radical transformations should the scholar community envision and advocate to implement in the next round of systemic reform? The next two sections explore these questions.

Using STEAM to improve educational experiences within the systemic constraints

Without denying the value of out-of-school programs, focusing on school settings has the potential to engage institutional structures serving many more children, including those that do not already have a science identity that led them to join an out-of-school

program and are therefore poised to benefit the most. The educational program being developed by these authors has been growing within, and in partnership with, actors in the formal school system, and the resources thus created are widely used in the US and are starting to be used globally (Akshay et al., 2020). Here, we draw on our experience growing the program (Minces, 2021) and our conversations with the STEAM leaders to address the implementation barriers.

A key factor for growing the program is the alignment with the curricular standards, which addresses the issue of curricular pressure mentioned in the previous section. Schools and teachers are oftentimes eager to implement resources that they perceive will engage their students, and will need a minimal measure of standards alignment to be able to do so. Therefore, the standard alignment can sometimes be rather loose, partial, or include STEAM experiences in combination with less meaningful materials. For example, our curricular resources integrate music when addressing the relationship between frequency and pitch, but are much drier when addressing the concept of *wavelength*.

Even allowing for loose alignments, some standards are so far removed from the children's everyday experiences that it cannot be expected that they will be addressed through an Authentically Thick STEAM project. In that case, a subservient art experience always offers the possibility of children making an art presentation about the standard, which might be better than the alternative.

With regard to teacher implementation, it is important that the resources help alleviate, rather than increase, the teachers' burdens. STEAM is a great opportunity to engage teachers, since they can also participate in the joy of the art-making process, which likely increases the likelihood that they will participate in teacher training. Resources should be extremely easy to start implementing, in what Resnick calls low floor (Resnick and Robinson, 2017), and allow for deeper engagement (high ceiling). A low floor includes activities requiring minimal or easily available material resources. For example, using web applications can be much more accessible than using downloadable software, which can be difficult to install on the schools' computers or on the students' devices. A low floor also means designing tools that are easy to use and that are engaging from the first moment. Involving teachers in the design process can be very helpful for fulfilling those goals (Minces, 2021). Another factor facilitating the implementation of STEAM experiences is to provide rubrics that allow teachers to guide the art-making process and evaluate the children's work with less reliance on testing, and with less time spent analyzing each artifact (for example, grading the children's compositions). Easing the implementation of a program will not only facilitate the work in the classroom but will also streamline the teachers' professional development. Regarding research, achieving broader implementation requires a shift toward policy-based research (List, 2022), that is, research that from the outset takes into consideration the possibility of scaling up the results.

A STEAM-inspired vision for education

The section above describes strategies for improving the children's educational experience within the limits of the educational system. This section discusses how STEAM can inform future rounds of systemic reform, which requires a reflection on what education is for (Biesta, 2015). The educational system does not have a clear overarching goal. Rather, it has adopted the goals of different stakeholders, which in turn might be different and contradictory (Labaree, 2012). The state might be interested in forming citizens with coherent national values and in developing the workforce to serve the economic and strategic needs of the country. Parents might value the educational system for providing a place for childcare and improving their children's economic outlook. Teachers might care about leading a classroom where students are intellectually engaged while complying with the school authorities by implementing the new set of standards and preparing children for the test. The goals for principals might be to manage the children's behavior and improve the schools' statistics by increasing the number of students pursuing higher education. Children have no choice but to participate in the system and, young children in particular, might not be so concerned about the future. They might be very interested in socializing, in not being bored, and in learning something, although not necessarily what they are expected to learn. An additional stakeholder, different from the child, is the adult that the child will be, which emerges slowly as the child approaches high school graduation and faces the need to sustain herself or himself. A goal for that adult is to have an occupation that provides life quality, which could involve economic well-being, intellectual fulfillment, or a sense of purpose. Successful reform must acknowledge and harmonize all these goals that at times appear to be in tension, in particular the state's goal for developing a specific type of workforce versus the children's personal interests. Our goal as researchers is to emphasize the interest of the children to help create a more joyful learning environment, without disregarding the interests of other stakeholders.

The policymakers' and society's interests are expressed in the curriculum and activities carried out in schools. In the United States and England, which have influenced educational systems and science education throughout the world, curricular subjects have been a matter of fiery debates and widespread reforms (Atkin & Black, 2007; DeBoer, 2014). Three main conceptual currents have informed those reforms, with elements of them alternating and taking prevalence over time. One current, dominating in the late 19 century, and referred to here as experiential, emphasized science practices and direct observation of everyday and natural phenomena. Another current, prevalent in the first half of the twentieth century in association with the progressive movement, and briefly reemerging in the sixties, emphasized the curricular subjects' value to society, value to the students, and technological applications in nascent industries. The present moment inherits the values of the education reform born during the cold war's fight for technological supremacy in the fifties, sometimes referred to as the Sputnik era of reform, and that regained strength in the eighties in the context of international industrial competition. The latter current reflected the value that society assigned to cutting edge scientific knowledge, and was shaped by the advice of prominent scientists, who advocated for including curricular subjects associated with the latest advances in their fields and the corresponding higher education courses, in what Atkin and Black

(2007) call “scientists’ science”. The latter era also saw a great increase in the value that society assigned to higher education (Baker, 2014), and in the number of people pursuing higher education, with the consequent need to sort what children could attend what institutions (Sandel, 2020). This confluence of factors produced a science and math curriculum that focuses on preparing children for pursuing careers in STEM through higher education paths, and sorting the children that can go through the hoops that such preparation requires. This ethos is captured in the popular model of STEM workforce development as a pipeline (Cannady et al., 2014; Metcalf, 2010), in which children enter at one end and emerge on the other as adult STEM professionals, with the problem that some children, those that cannot go through the hoops, drip off the pipeline, which is therefore referred to as being leaky. We note that the pipeline model is partially different in some countries in which an early tracking system sorts children putting them on a path to higher education or to technical careers through vocational schools. Such a system, which could be modeled as a bifurcating pipeline, has the advantage of producing a large pool of necessary mid-skilled labor and offering young people a safe path to economic security (Newman and Winston, 2016), but it has the disadvantage of sorting children early in life, making it difficult for someone to change and cross trajectories, perpetuating social differences, and creating resentment.

Given that the majority of children, particularly low-income children, will not finish a higher education degree, and a very large majority will not pursue a higher education STEM career, a strong focus on higher education science implies that they will spend a large portion of their time studying curricular topics that are not relevant to their lives or future occupations, that they might be resentful of being sifted-out in their science and math classes, and that by early adolescence they will lose confidence in their capacity to participate in the STEM world (Tai et al., 2006). The pipeline model does not serve the interest of society and the government either, since the exaggerated focus on preparing children for higher education in STEM fields: (a) fails to engage enough children in higher education STEM pathways (b) fails to produce the necessary mid-skill STEM practitioners that the workforce also needs and that can provide young people with a decent living wage (Newman and Winston, 2016), (c) fails to give children the tools to engage with STEM in their everyday lives, and (d) generates negative attitudes toward science, which might explain the current resentment and suspicion by a large part of the population toward the scientific community (Atkin & Black, 2007). Furthermore, it is not clear that the curricular topics being emphasized at a moment in time will be the most relevant for the workforce of the future, for example, data science and statistics are arguably more valued in the workforce today than calculus, but are not as prominently represented in the curriculum. In other words, education today prepares the workforce of the future for the jobs of the past.

The problems with the pipeline model and the intense focus on higher education topics are being recognized by the education community, as expressed by Atkin and Black: “As it is realized that scientists’ science, oriented toward the painstaking construction of conceptual frameworks that explain how the world works, is of limited use to the vast majority, new ways of enabling the citizenry to comprehend and operate in a scientific and technological culture have to be sought”. With this understanding, in the later years the education community has been striving to promote project-based learning and culturally responsive education (Ladson-Billings, 2014), conceptions from which STEM and STEAM education derive, and which are associated with the values prevalent in the experiential and progressive eras. Those efforts crash against curricular subjects that are too obtuse, for example, it is hard to think of a culturally responsive and experiential way to explore the difficult concepts of wavelength or the particle-wave duality of light, which, it can be argued, is not even understood by professional physicists (Ballentine, 2014). An additional problem of these obtuse standards is that being poorly understood by teachers and curriculum developers, they are reflected in superficial activities that misinterpret the natural phenomena that they are meant to explore, and that can only be accomplished through rote memorization (Fig. 2), which removes the children’s agency as understanders and inquirers. Those traditional curricular topics are decontextualized, in the sense that neither children nor teachers know why they are important or how they can be applied to their lives, which deprives children of a motivation to learn them other than to continue their academic life. Studying subjects without a clear motivation, especially for students that are not driven by grades and do not aspire to pursue higher education, is tedious and hard, or, as the Sputnik era discourse often calls for: rigorous (from Latin *rigorem*, meaning stiff). The emphasis on rigor as a primary value is surprising, since there is no indication that rigorous work produces more meaningful knowledge, and on the contrary, the less meaningful the knowledge the more rigorous study it requires.

Fig. 2 STEAM versus traditional schooling practices. Left, typical test given to children to assess their knowledge of waves. Note that the axes do not have labels so it is not clear what the line is representing. Teachers can administer the test and students can comply, even without understanding the meaning of the concepts. Right, children create musical compositions using a sound editor and oscilloscope (see list of relevant websites). Through this activity children can learn to measure, visualize, and manipulate signals, which are ubiquitous practices in science and engineering, and improve their data literacy (Akshay et al., 2020).

In contrast to rigor as a primary value, STEAM education offers curiosity, passion, and the aesthetic experience (Booker and Minces, 2022; Milne, 2010), values that more faithfully reflect the experience of scientists and artists, for whom rigor is secondary to the pursuit of those passions. Through its connections with the arts, STEAM education signals a way for choosing curricular topics that are personally relevant to the child. Importantly, if the community gets past their rigid expectations of what science should look and feel like, it can be understood that Thickly Authentic STEAM topics are not any less science than other traditional curricular topics. For example, understanding how objects vibrate, how microphones work, or how to read and manipulate signals is not any less science than understanding the concept of wavelength (Fig. 2). And because Authentically Thick STEAM activities are contextualized in personal goals they are less prone to misinterpretation. In our example, a child needs to understand how to read and manipulate a signal to achieve their artistic goal of creating a sound composition. Through such activities, all children can engage with STEM as creators, develop agency and positive attitudes toward STEM, acquire knowledge that allows them to reinterpret their everyday environment—in our example, popular music—and gain skills that they can immediately apply, so they never need to ask “what are we doing this for?”. These experiences are directed at enriching the lives of all children, rather than the selected few that will follow a STEM higher education path, and these experiences are actually likely to increase the proportion of children that follow that path. Furthermore, the skills gained can be extended into other STEM fields that are highly valued in the workforce, as the Earsketch music coding platform (Freeman et al., 2014) or these authors’ data literacy work indicate (Akshay et al., 2020).

STEAM calls for rethinking the curricular topics to move them from decontextualized and impersonal to contextualized and personally relevant. Possibilities abound, as children work on woodworking projects they can learn algebra and geometry, develop their spatial intuition, explore the properties of materials and learn to design for structural stability; if they have access to laser cutters or CNC routers they can learn fabrication technologies and digital design. Importantly, they will be learning woodworking. Children can also learn electronics in the context of clothing design (Peppler, 2013), computing in the context of videogame design (Resnick and Robinson, 2017), optics in the context of photography, chemistry in the context of cooking and painting (through the creation of pigments) and, in the spirit of Leonardo, biology and geometry in the context of drawing.

The examples above point to a need to modify the academic structure to reflect project goals rather than siloed academic fields – for example introducing sound production, computer music, video game design, or woodworking classes – and to rethink the teacher workforce to include domain practitioners rather than teachers that do not have practical expertise in the fields they are teaching. Through these activities and personal interaction with practitioners, children can become aware and start exploring possible career occupations more immediately available to them after high school, such as carpentry, or that require further academic training, such as structural engineering.

This vision for education has many commonalities with vocational schooling. This is not a coincidence, since they both share the philosophy of goal-based and situated work. Mainstream schooling has a lot to learn from vocational schooling, which when implemented properly can provide mid-skill workers for the economy and has been shown to decrease school attrition and lead to good employment for young people, particularly for the many children that do not thrive in a less contextualized academic environment (Newman and Winston, 2016). As opposed to vocational education, however, this vision puts a heavier emphasis on creativity and personal meaning, and does not call for the highly specialized technical education that could limit young people’s career choices.

Thickly Authentic STEAM practices also call for shifting the way students’ capabilities are assessed, away from tests (Fig. 2) and toward performance assessments in which children demonstrate their learning through the artifacts they create (Bland and Gareis, 2018). This shift can also allow students to create a personal portfolio which can be useful in securing future employment.

The proposals above defy the role of K12 education as a sorting mechanism for higher education. This is problematic within a system that values higher education credentials in terms of social status and in terms of economics, as higher education degrees are requisite for high-paying jobs (Baker, 2014; Collins, 2019). However, these proposals might better accompany current trends in higher education and the world of work, which have been under increasing pressure – and perhaps recognize the need – to become more inclusive of social groups traditionally underrepresented. In response to that pressure, several prestigious universities have been reevaluating their admission practices to be less reliant on traditional measures of capability (Hubler, 2020; Sandel, 2020) that favor high-income applicants; and as private companies and governmental institutions have struggled to find capable employees, they have been steadily expanding hiring practices that are less reliant on the applicants’ credentials than on their skills, in what is referred to as skill-based hiring (Ark, 2021; Lohr, 2022), which can be well developed through STEAM practices and well represented through the students’ portfolios.

Conclusion

The school system appears to be in tension between an instrumentalist conception of education as a workforce factory and a humanistic conception that forefronts the children’s well-being and intellectual development. Part of this tension arises from society’s narrow views of what STEM and the arts should look like, and what are the paths necessary to get to them. The conception of STEM paths as a pipeline into higher education has deprived children of the possibility of experiencing STEM fields as fascinating and useful, alienated them from STEM, and done little to achieve its expected goal of developing the workforce. By opening the field of vision and recognizing the many ways in which children can engage creatively in STEM fields through the arts, STEAM education can harmonize that tension, engaging more diverse children in STEM paths, bringing them value and skills that they can readily use, and contributing to making their school experience more joyful.

Acknowledgments

We are grateful for the input from the following San Diego STEAM leaders: Michael Goodbody, director for STEAM Innovation at San Diego Unified School District; Leo Ulloa, STEAM coordinator at Sweetwater High School Unified School District; Victor Ciciarelli, creator of the STEAM maker space and STEAM maker fair, which draws 30,000 children annually; Karyn Warner and Glennon Stratton, associate director and director of STEAM initiatives at the CDE-Foundation, which provides STEAM professional development for teachers in California and throughout the world; and Alec Barron, director of the San Diego Science Project and former science content specialist at Escondido Union High School District. We are also grateful for the historical insights provided by Donald Peurach and the careful editing by Laleh Quinn. Minces' work is funded by the National Science Foundation's Innovative Technology Experiences for Students and Teachers (ITEST) #2048930. Increasing Students' Interest in STEM through the Science of Music.

Introduction

With the rise of STEM education as a way to develop students' 21st century skills (Binkley et al., 2012; Johnson et al., 2020; Maass et al., 2019a,b), the role that mathematics plays in STEM teaching and learning has drawn increased attention. One of the biggest concerns is that mathematics is largely underrepresented in STEM education even though it is commonly acknowledged as a foundation for STEM activities (English, 2016; English and Kirshner, 2016; Honey et al., 2014). Often, mathematics is treated as a set of given procedures or tricks that help students complete STEM activities (Li and Schoenfeld, 2019). Such an approach to mathematics learning leads to the loss of opportunities to develop mathematical thinking (Wong and Dillon, 2019). Not surprisingly, STEM activities were found to be beneficial for other disciplines, mainly science, but rarely for mathematics (Fitzallen, 2015; Honey et al., 2014; National Research Council, 2014). Consequently, the field of mathematics education calls for making mathematics explicit in STEM activities (Larson, 2017; Maass et al., 2019b; National Council of Supervisors of Mathematics & National Council of Teachers of Mathematics [NCSM & NCTM], 2018; Shaughnessy, 2013; Silk et al., 2010). For instance, NCSM and NCTM (2018) stress the importance of teaching mathematical content and process well when tackling integrative STEM problems: "Whenever mathematics is included in a STEM activity, make sure that the mathematics addresses academic standards appropriate for the grade level and that it is taught in ways that support the development of mathematical thinking and quantitative reasoning" (p. 4). Indeed, when the relevant mathematical aspects are addressed appropriately and deeply, students' interests and dispositions toward STEM could be ignited. This is a critical component in the STEM field (President's Council of Advisors on Science and Technology [PCAST], 2010). Building on the perspectives advanced by NCSM and NCTM (2018) as well as other recent literature, we explore how critical aspects of mathematical content and process can contribute to STEM education, as well as how it can be made explicit to students. To explore these mathematical aspects within STEM education and provide context for our research focus, we start with a broad overview of the relationships between mathematics and STEM education.

The relationship between mathematics and STEM

According to NCSM and NCTM (2018), mathematics, with its unique contents and connections to non-STEM fields, does more than serve as a tool for STEM. We propose Fig. 1 to illustrate the relationship described by NCSM and NCTM (2018):

Teaching mathematics well is an important component of a comprehensive STEM program. There is more to mathematics, however, than being part of STEM. The mathematics that students learn in school includes content and thinking that can be used as tools for tackling integrative STEM problems. But it also includes content that might be considered "just math" or might be connected to non-STEM disciplines (p. 3).

Fig. 1 Illustration of NCSM and NCTM's (2018) position about mathematics and STEM.

In Fig. 1, the three sections refer to mathematics only, STEM only, and the intersection of mathematics and STEM. On the one hand, some mathematics concepts are “pure math,” concepts that originated without a connection to STEM. For example, the axiom and propositions in Euclidean geometry were defined within its own system (Fitzpatrick, 2007). On the other hand, the STEM fields (excluding M) contain unique phenomena, concepts, and rules that may not have a relationship to mathematics. For instance, the fact that plants need sunlight, water, and air to grow is a science phenomenon that exists regardless of mathematics. Importantly, the intersection between mathematics and STEM provides an understanding of the depth and interconnectedness of the two. For instance, the STEM field provides real-world contexts in which mathematics are applied and developed, while mathematics serves as a tool to describe and explore the STEM fields.

In this article, we focus on the intersection between mathematics and STEM. Specifically, we aim to discuss mathematics in STEM education in K–12 classrooms. Ideally, mathematics learning can contribute to the success of STEM education, which in turn boosts the learning of mathematics. However, empirical studies indicate challenges with mathematics in STEM lessons. For instance, science teachers found that their students lacked important mathematics knowledge needed to successfully conduct science activities (“math blame,” Wong and Dillon, 2019). On the other hand, mathematics teachers noticed that rich opportunities to discuss mathematical concepts diminished in science courses (Wong and Dillon, 2019). In fact, researchers are concerned that mathematical concepts and reasoning are often lost in STEM activities, which does not benefit mathematics learning (Becker and Park, 2011; Honey et al., 2014). Fitzallen (2015) further argued that even though many STEM projects claimed that mathematics was involved in their projects, the ways in which “mathematics can influence and contribute to the understanding of the ideas and concepts of other STEM disciplines” (p. 241) were not addressed. In this article, we aim to narrow this gap by discussing how mathematics may contribute to STEM activities.

Mathematics in STEM

Theoretical frameworks

Fig. 2 presents two existing theoretical frameworks that together guide our study:

Fig. 2A is an illustration taken from Maass et al. (2019a), which zooms out on the role of mathematics in STEM reality. In this model, a real-world situation can be simplified into a situation model, which can be further mathematized (as illustrated by the “mathematizing” arrow at the top of the figure) to generate solutions. Conversely, mathematical solutions can be interpreted to help solve targeted STEM problems (as illustrated by the “interpreting” arrow at the bottom of the figure). The model in Fig. 2A raises the question, “What are the exact mathematical elements that play a role in STEM?” As mentioned earlier, NCSM and NCTM (2018) stress that both the content and process of mathematics should contribute to STEM learning. The Program for International Student Assessment’s (PISA) 2022 mathematics framework (Fig. 2B; Organization for Economic Co-operation and Development [OECD], 2018) offers more details about the specific elements of mathematics that play an important role in STEM education. The PISA 2022 framework identifies four targeted content areas (*quantity, uncertainty and data, change and relationship, and space and shape*) that are basically consistent with NCTM’s (2000) five content standards (*number and operations, algebra, geometry, measurement, and data analysis and probability*). The framework also highlights the cyclical process of problem-solving (or modeling): *formulate, employ, and interpret and evaluate*. The center of the problem solving cycle is mathematical reasoning.

Using these theoretical frameworks, we now discuss how mathematical content and process may contribute to STEM activities. Although mathematical content and process cannot be separated, for clarity we discuss each aspect in a separate section. Specifically, we argue that the content of mathematics can serve as a language tool for STEM activities, while the process of mathematics serves as a thinking tool for STEM experiences.

Fig. 2 Theoretical frameworks used in this study. (A) Role of Mathematics in STEM (Maass et al., 2019a,b, p. 875). (B) PISA 2022 mathematics framework (OECD, 2018).

Mathematics as a language tool in STEM education: the content

Mathematics serves as a language tool to describe, represent, and communicate about STEM activities (e.g., Dantzig and Mazur, 2007). Just like any other language that has a vocabulary, grammar, and syntax, mathematics has numbers, symbols, and concepts that operate upon certain rules. Using this mathematical language, one can represent and model real-world situations in the STEM field, producing results that can be discussed globally. In K–12 classrooms, each of the NCTM's (2000) five content standards (or PISA 2022 framework's four content areas) were involved in the reported STEM activities. For instance, NCTM's teaching journal, *Mathematical Teaching in the Middle School*, published a special issue in 2013 that contained six studies. Students in these studies participated in activities such as "building a robot, playing a battleship-like game, designing a staircase, analyzing crystalline-structure data, constructing weight-bearing tables out of paper, and designing a skate park" (Shaughnessy, 2013). Through these activities, students were able to employ a variety of mathematical content including geometry (or "space and shape"; Allen, 2013; Enderson and Grant, 2013); algebraic concepts (or "changes and relationships") such as Cartesian coordinates (Kranz et al., 2013), slope (Smith et al., 2013), ratio and proportional thinking (Stoner et al., 2013); statistical concepts (or "uncertainty and data") such as average (Magiera, 2013); and measurement (Enderson and Grant, 2013; Stoner et al., 2013). Similarly, the journal of ZDM—*Mathematics Education* published a special issue on STEM education in 2019 containing three studies conducted in elementary schools. The STEM activities (e.g., using motion detectors, computer programming-coding, and measuring plant growth) involved varied mathematical concepts such as reasoning about graphs (Duijzer et al., 2019), pattern recognition (Miller, 2019), and measurement using rulers (Geiger, 2019). Of course, in all of the previously mentioned activities, numbers and operations (or "quantity") were involved as part of the computations. However, since these examples depict a rich but broad picture of the relationship between mathematics and STEM education, the precise contributions of mathematics to STEM activities may not yet be clear. We would like to highlight two major roles that mathematics content can play in STEM education: (a) representing and modeling, and (b) interpreting and explaining.

Representing and modeling

First, mathematical content can play a role in STEM activities when concepts are used to help represent and discuss real-world situations (see Fig. 2A). Consider, for example, creating and analyzing graphs for STEM activities that involve technology. Duijzer et al. (2019) reported how primary school students (fifth graders) worked in front of a motion sensor to generate distance-time graphs. A similar activity was reported by Smith et al. (2013) with eighth graders. Using students' motions (moving, moving slowly, spinning, and standing still), a motion detector generated different graphs that represented the relationship between distance and time. In these STEM activities, mathematics (in this case, graphs) was used to describe students' body movement or the distance they walked in relation to time. As acknowledged by both studies, the underlying mathematics concept behind these graphs is related to the concept of slope and rate of change. This is an important algebraic concept in middle school and beyond (Leinhardt et al., 1990). In both studies, some of the generated graphs indicated a linear relationship while others indicated a non-linear relationship. Together, these graphs showed the functional relationship between the two related variables (time, distance), which are just as important as their algebraic representations (Leinhardt et al., 1990). STEM activities without the support of technology also demand students' use of mathematics to represent and model them. Enderson and Grant (2013) introduced an engineering design activity in

which seventh graders were asked to construct a paper table. To prepare them for their table design, students were first instructed to engage in exploring the properties of various polygons (e.g., quadrilaterals) and the connections between their strength and polygon properties. These geometrical concepts provided students with the necessary tools to successfully represent their table designs and to communicate with their peers about their design products.

Interpreting and explaining

The second role that mathematics content can perform in STEM activities is interpretation and explanation. How did a STEM phenomenon occur? Why did it occur? Will the observed pattern always be true? Why is one situation/design better than the other? How can adjustments make it better? To best understand these STEM activity questions, mathematical content/concepts serve as critical elements for reasoning, which in turn contribute to the interpretation of STEM phenomena (see Fig. 2A). Geiger (2019) shared how a science teacher, Stef, guided her first graders to explore the growth of bean sprouts under different levels of sunlight while holding other variables constant. To discuss the critical question, “What did we do/what could we have done to make the seeds grow better?” (p. 935), the class measured and compared the length of the bean sprouts under different conditions. This provided mathematics-based evidence (length determined by measurement) to help interpret and explain the science behind this phenomenon. In addition, Smith et al. (2013) reported an engineering activity in which eighth graders were instructed to explore the steepness of staircase. Students worked in small groups to measure the height and depth of two steps on a staircase. They were also asked to compare the ratio of the two measurements and discuss how they can make the staircase more or less steep. Students produced a variety of observations, yet only one group noticed that the ratio of the two measures remained the same. A follow-up discussion revealed students’ misconceptions about how to correctly use a ruler (e.g., measuring at the end of the ruler rather than the “0” marking) and why students produced inconsistent results (due to the use of two different units, inches and centimeters). After addressing the mathematical obstacles, the class reached the consensus that the ratio between height and depth would stay the same. This shed light on the underlying concept of slope that further explained the steepness of the staircase in an engineering context. In fact, students in that class also mentioned other real-world situations such as wheelchair-access ramps and how they can be explained by the same mathematical concept. In both examples above, the targeted mathematical concepts (length, slope) served as tools to help interpret and explain the science phenomenon and engineering design.

Mathematics as a thinking tool in STEM education: the process

In addition to serving as a language tool, mathematics also serves as a thinking tool for STEM activities. As Honey et al. (2014) noted, STEM activities are typically accomplished through the use of problem, project, and design-based tasks that are situated in real-world contexts. As such, problem solving is an important process that occurs in K–12 STEM classrooms, as illustrated in published empirical studies (e.g., Allen, 2013; Geiger, 2019; Magiera, 2013; Stoner et al., 2013). In the field of mathematics education, problem solving is also viewed as one of the critical mathematical processes for student learning (e.g., NCTM, 2000; National Governors Association Center for Best Practices and the Council of Chief State School Officers [NGAC & CCSO], 2010). As such, mathematical problem-solving competency, if well developed and utilized, can contribute to STEM education. Students in STEM need to make sense of the given real-world situations, formulate mathematical models based on data, and interpret and evaluate mathematical solutions to make critical decisions. As mentioned earlier, these processes in problem solving (formulate, employ, and interpret and evaluate) are clearly highlighted in PISA’s 2022 mathematics framework (see Fig. 2B). In some sense, these processes are similar to Polya’s (1945) seminal work on mathematical problem solving, which stressed four heuristic processes (understand the problem, devise a plan, carry out a plan, and look back) and general strategies (e.g., look for a pattern, draw a diagram, use a model, work backwards). However, mathematics education research shows that a focus on heuristics and general strategies does not contribute to students’ problem-solving competency (Begle, 1979; Cai, 2003; Cai and Lester, 2010; Lesh and Zawojewski, 2007; Schoenfeld, 1992; Silver, 1985). In the same vein, a focus on general mathematical problem solving processes may not contribute to STEM education. This might also be a reason why PISA’s mathematical framework has placed “mathematical reasoning” in the center of the problem solving cycle (see Fig. 2B). In addition, with the increasing use of information, computer, and technology (ICT) in current K–12 classrooms, computational thinking adds one more layer of meaning to problem solving and reasoning. PISA’s 2022 mathematics framework clearly expects that students understand computational thinking and can apply mathematical reasoning in technological contexts (OECD, 2018). Computational thinking is not only expected for the upper grade students (e.g., high school and college) but also for children in early years (Grover and Pea, 2013, 2018; Lye and Koh, 2014; Wing, 2006, 2008, 2011). Given that mathematical reasoning and computational thinking are critical (Binkley et al., 2012; Maass et al., 2019b; OECD, 2018), below we discuss how these two thinking skills play a role in K–12 STEM classrooms.

Mathematical reasoning

Mathematical reasoning can be either deductive or inductive, which is enabled by the following key understandings that undergird school mathematics (OECD, 2018):

- Understanding quantity, number systems and their algebraic properties;
- Appreciating the power of abstraction and symbolic representation;
- Seeing mathematical structures and their regularities;

- Recognizing functional relationships between quantities;
- Using mathematical modeling as a lens onto the real world; and
- Understanding variation as the heart of statistics (p. 15).

As such, instead of teaching general problem solving strategies, current mathematics education advocates teaching mathematics through problem solving (e.g., Cai, 2003; Cai and Lester, 2010; Cai et al., 2005; English and Sriraman, 2010; Lester, 1994), which lends opportunities to stress mathematical reasoning as a key process. Through solving mathematically rich problems, students will learn mathematical concepts and ideas, which in turn develops students' key understandings and reasoning skills (Cai, 2003; Cai and Lester, 2010). By "mathematically rich problems," Cai and Lester (2010) referred to tasks that are "open ended and allow for multiple correct answers and multiple solution approaches" (p. 257). However, as reviewed earlier, many STEM lessons do not actually involve mathematical reasoning. Rather, mathematics is only presented and utilized as a set of procedures or tricks (Wong and Dillion, 2019). In fact, this is also an issue for some solely mathematics lessons in K–12 classrooms (Li and Schoenfeld, 2019).

To address these issues, there is a call for "modeling" (English, 2016; Maass et al., 2019b) and "sense-making" (Li and Schoenfeld, 2019; Zhao and Schuchardt, 2021) to advance students' mathematical problem solving and reasoning. Doerr and English (2003) defined models as "systems of elements, operations, relationships, and rules that can be used to describe, explain, or predict the behavior of some other familiar system" (p. 112). English and Sriraman (2010) explicitly emphasized that "modeling problems are realistically complex situations where the problem solver engages in mathematical thinking beyond the usual school experience" (p. 273). This modeling process demands that students awaken and use their reasoning skills. In fact, English also provided examples regarding how mathematical models and reasoning are used with available data to make critical decisions for realistically complex problems such as an aerospace task (English and King, 2015). With regard to sense-making, various models were also developed to illustrate how reasoning skills are needed for both mathematics and STEM lessons (Li and Schoenfeld, 2019; Schoenfeld, 2020; Zhao and Schuchardt, 2021).

Unfortunately, these types of mathematical reasoning skills are often missing from STEM activities. Consider, for example, the aforementioned motion sensor graphs. In some of the STEM lessons (Duijzer et al., 2019; Smith et al., 2013), the technology-generated graphs were directly given to students. While the power of technology should be acknowledged, these instances also show how mathematical opportunities could have been better grasped. Leinhardt et al. (1990) pointed out that computer-generated graphs may not support student learning in subtle ways; rather, "students may develop too strong a reliance on the machine. For example, they may not understand the underlying patterns and principles that drive the production of the graphs" (p. 7). Even without technology support, some STEM teachers still simply give out graphs or needed mathematical procedures to complete science activities. Wong and Dillion (2019) reported that a secondary mathematics teacher in England made the following reflection after she observed a science lesson in her school:

And rather than talk to the students about what sort of data they were collecting and therefore what would be the best way of them representing that data and getting them to think about it [...] they were told instantly [...] "and at the end of this, you are going to draw a graph and it's going to look like this." And I just thought it was a missed opportunity [...] "Why would you want to do this graph?" [...] that discussion about why and where that comes from, from the data, those discussions didn't tend to happen (p. 793).

Interestingly, in the same study, one science teacher complained about how her secondary students lacked the ability to create graphs: "loads of them had issues drawing the axes on their graph and doing the scale properly, then plotting the graph, then drawing the line of best fit." (p. 790). Due to the lack of necessary mathematical skills, the science teacher was unable to complete her science learning objectives. The above stories indicate how mathematical reasoning should be utilized and facilitated during the process of solving STEM problems.

Computational thinking (CT)

Computational thinking is a critical way of problem solving that involves many elements of 21st century skills (e.g., systems thinking, information use, critical thinking, creativity, communication, see Fig. 2B). In her seminal work, Wing (2006) clarified what CT is and is not. CT is a way that humans solve problems rather than trying to get humans to think like computers. It is about conceptualizing rather than programming. Being able to program a computer is not CT; CT demands multiple levels of abstraction. In other words, even though CT involves the use of computers, it is different from the use of technology. Additionally, CT is not exactly the same thing as mathematical thinking (Grover and Pea, 2013) even though "its formal foundations rest on mathematics" (Wing, 2006, p. 35).

So, what is computational thinking? Although there is no consensus on the definition of CT (Cutumisu et al., 2019), Wing (2011) defined computational thinking as "the thought processes involved in formulating problems and their solutions so that the solutions are represented in a form that can be effectively carried out by an information-processing agent" (p. 1). Aho (2012) further updated this definition, making its mathematical feature more explicit: "computational thinking is the thought processes involved in formulating problems so their solutions can be represented as computational steps and algorithms" (p. 832). An algorithm "is an abstraction of a step-by-step procedure for taking input and producing some desired output" (Wing, 2008, p. 3718). This is clearly related to functional thinking in mathematics. These abstractions (computational steps and algorithms) are the essence of computational thinking (Aho, 2012; Grover and Pea, 2013). Wing (2011) explained that abstraction

is about defining patterns and generalizing from the specifics. [Grover and Pea \(2018\)](#) stated that abstraction “is a general property of symbolic systems that has been leveraged in arithmetic, algebra and other mathematical sub-domains for centuries” (p. 25). These definitions indicate how closely CT is related to mathematics.

Since [Wing \(2006\)](#) views computational thinking as “for everyone, everywhere” (p. 35), computational thinking has drawn increased attention in K–12 classrooms ([Barr et al., 2011](#); [Grover and Pea, 2013, 2018](#); [Lye and Koh, 2014](#); [NRC, 2012](#)). The [National Research Council \(2012\)](#) in its framework for K–12 science education listed “mathematics and computational thinking” as one of the eight practices for science and engineering:

Mathematics (including statistics) and computational tools are essential for data analysis, especially for large data sets. The abilities to view data from different perspectives and with different graphical representations, to test relationships between variables, and to explore the interplay of diverse external conditions all require mathematical skills that are enhanced and extended with computational skills (p. 65).

More recently, [Grover and Pea \(2018\)](#) proposed a competency framework that contained CT concepts and CT practices, which enabled further research on CT in K–12 classrooms. Among the six CT concepts, four of them—logic and logical thinking, algorithms and algorithmic thinking, patterns and pattern recognition, abstraction and generalization—are mathematically driven. Empirical studies also indicate that different tools are used in K–12 classrooms to develop students’ CT and associated STEM skills. For instance, graphical programming environments such as Scratch and Alice are widely used in classrooms to allow early experiences with CT ([Grover and Pea, 2013](#)). [Miller \(2019\)](#) reported how second graders (ages 7–8) in Australia were taught to do coding activities using Scratch or coding robots. Through these activities, students were expected to develop not only computational thinking but also mathematical understanding of patterning and structures as well as generalization skills, which are underpinnings of algebraic thinking ([Kaput et al., 2008](#)).

As grade level increases, robotic kits are used more commonly in classrooms. For instance, [Allen \(2013\)](#) reported how middle school students learned to create a robot in mathematics classrooms. Consider, for example, if students wanted their robot to “launch via a clap, roll forward 10 inches, make a 90° right turn, continue rolling until it hits a black line, and stop” (p. 343). To make their robot carry out these actions, students needed to decompose this task into smaller steps and write icon-based programs. This is where mathematics (or “abstraction”) is involved. For instance, students need to figure out how far the robot travels with one rotation of the wheels (circumference) and how many rotations are needed to complete 10 inches. They also need to use multiple sensor inputs, define variables, and reason proportionally. Furthermore, they need to use inequalities to make their robot start, turn, and stop in the exact desired locations. As [Allen \(2013\)](#) reported, through the above robotics activities, students were motivated to learn mathematics and develop their CT skills. This example addresses the challenge proposed by [Wing \(2008\)](#) on computational thinking, “we do not want the tool to get in the way of understanding the concepts. We also do not want people just to be able to use the tool but not have learned the concepts” (p. 3721). It should be noted that in this study, students’ computational and mathematical thinking also contributed to other STEM activities (e.g., the engineering component of building a robot).

Implications: what do we learn from the current research?

The above discussion of the roles of mathematics in STEM, as (a) a language tool and (b) a thinking tool, provides direction for enhancing and strengthening future STEM lessons. As mentioned earlier, the current field is largely concerned that mathematics is often diminished and lost in STEM activities ([English, 2016](#); [Honey et al., 2014](#); [Larson, 2017](#); [NCSM and NCTM, 2018](#); [Maass et al., 2019b](#); [Shaughnessy, 2013](#); [Silk et al., 2010](#)). Perhaps STEM classrooms can devote more time to explicitly addressing the above two roles that mathematics play in STEM activities. Below we have highlighted a few specific in-class actions that can help educators work toward this goal.

Setting up grade-appropriate mathematics learning goals in STEM lessons

First, there should be clear mathematical learning objectives in each STEM lesson. This is because mathematics is a foundation of STEM education ([NCTM and NCSM, 2018](#)). Furthermore, setting goals can help to ensure that mathematics learning also benefits from STEM lesson activities ([Honey et al., 2014](#)). More importantly, the mathematics involved should be targeted toward the content standards appropriate for each grade level ([Larson, 2017](#); [NCTM and NCSM, 2018](#)). To illustrate this point, we revisit the aforementioned articles by [Duijzer et al. \(2019\)](#) and [Smith et al. \(2013\)](#). Both articles used a motion detector to generate distance-time graphs. While the former study involved fifth graders (primary in Australia), the latter involved eighth graders (secondary in the US). Likely due to the grade-level differences, the former study only focused on the interpretation of the graphs while the latter brought forth the concept of slope. Although both studies provide interesting findings, we are uncertain of whether the activity in [Duijzer et al. \(2019\)](#) was grade-appropriate as there was no introduction to Australia’s mathematics standards. In fact, even though this STEM lesson spanned six lessons, mathematics content was limited to graphs without a connection to any equations. This, again, is likely due to the grade-level constraint. As such, it is important to consider grade level when choosing STEM activities.

Setting up grade-level-appropriate math learning goals is especially important when taking STEM activities from other countries. For instance, an inspection of the Common Core State Standards in the USA indicates that students are expected to understand the

relationship between dependent and independent variables (using graphs, tables, and equations) in sixth grade. In addition, it is not until eighth grade that students are expected to graph proportional relationships and interpret the unit rate as the slope of the graph. Therefore, if a teacher is interested in using activities similar to those found in [Duijzer et al. \(2019\)](#), it might be better to postpone them to a later grade. In doing so, teachers could plan deeper, more thorough learning objectives and could make sure that graphs could be linked to mathematical equations. This linkage between graphs and equations is critical for future algebraic learning, one example being proportional reasoning and functions ([Leinhardt et al., 1990](#)). The grade-level appropriate learning goals are also a challenge when developing computational thinking in K–12 classrooms, which is a quite new area that demands much attention for both research and practice ([Wing, 2008](#)).

Promoting explicit mathematical connection-making in STEM lessons

Our second suggestion is to make explicit connections between the concrete representations (e.g., real-world situations, graphs, tools) and abstract mathematical models/solutions through lesson discussion. We believe such a connection-making structure not only highlights the role of mathematics in STEM, but also promotes students' mathematical reasoning and problem-solving skills. In the aforementioned staircase example that led to the concept of slope, [Smith et al. \(2013\)](#) reported that the class discussed slope "from both geometric and algebraic standpoints." However, it is unclear whether the staircase was modeled with geometrical figures, if an algebraic equation (e.g., $y = mx$) was introduced, and whether the geometric and algebraic representations were explicitly connected for students to best learn about the concept of "slope." In fact, the eighth grade CCSS standards suggest that teachers "use similar triangles to explain why the slope m is the same between any two distinct points on a non-vertical line in the coordinate plane" ([NGAC and CCSSO, 2010](#), p. 54). In the staircase activity, students were asked to compute different ratios between the height and depth of the steps. If a teacher was to guide students and explicitly model this activity, students would generate similar triangles that could be recorded algebraically (e.g., $\frac{y^2 - y^1}{x^2 - x^1} = \frac{y^4 - y^3}{x^4 - x^3}$). This proportional reasoning can, then, be used to explain why the slope (m) remained the same. In this way, geometric and algebraic connections are made explicit.

Another example that stresses explicit mathematical discussions is related to the measurement activity that frequently occurred in science classrooms. Studies across grade levels (from elementary to secondary schools) reported that students had misconceptions with using rulers (e.g., not starting with the marking of "0") ([Geiger, 2019](#); [Wong and Dillion, 2019](#); [Zhang et al., 2015](#)). For this reason, teachers in STEM classrooms should not assume that students have these basic skills to use these mathematics tools. Rather, explicit classroom discussions need to occur either before or after the STEM activities. Depending on the grade level, a teacher may explicitly prompt students to consider the following questions: Why can we not measure an object from the end of a ruler? What can we do if a ruler does not include the marking "0"? What does a marking on a ruler actually mean? What is the relationship between the unit sizes (e.g., inches or centimeters) and the resulting measurements (the inverse relation of a bigger size yielding smaller measures)? Discussions of these seemingly simple content questions will not only ready students for STEM activities, but also prompt their mathematical reasoning skills. Likewise, in technology-related classrooms, the grade-level computational concepts (if they exist) should also be made explicit for students, which is a challenge posed by [Wing \(2008\)](#) in terms of balancing between tools and concepts.

Developing a habit of mind of mathematical reasoning for STEM lessons

To develop students' mathematical reasoning, we think that there is a need to cultivate such a habit of mind even outside the STEM classes. [English \(2016\)](#) urged the field to explore "how we might best develop in-depth understanding of core mathematics content and processes within STEM experiences, while at the same time acknowledge that not all of mathematics can or should be learned within an integrated program" (p. 4). In other words, mathematical reasoning skills (including sense-making and modeling) can be developed in regular mathematical lessons through problem solving. [Ding \(2021\)](#) reported that Chinese expert teachers prompted students to attempt to reason about a problem situation in different ways, resulting in different solutions. This was even done with routine word problems, those with only one correct answer. Such reasoning skills, once becoming a habit of mind, will contribute to STEM lessons. In fact, mathematical reasoning demands students' sense-making, which can also be developed in regular mathematics lessons. [Ding \(2021\)](#) described a Chinese fourth grade lesson in which students were formally introduced to the commutative property of addition. In this lesson, the teacher changed a "." to a "?" at the end of a written statement about the commutativity, which was derived from students' discoveries based on one real-world example. This action elicited a heated class discussion, "How can we make a generalization based on just one example?" "Will this always be true?" "Can we find more examples?" "Can we exhaust all examples?" "How can we prove it?" "If we cannot prove it, can we find a counter-example to disprove it?" These reasoning, sense-making, and critical thinking skills, as prompted by the teacher's deep questions, are vital for conducting STEM activities. For instance, in [Smith et al. \(2013\)](#), students identified that the ratio between height and depth are the same. Using the above Chinese lesson example, we believe that students could have been challenged to ask deep questions such as: "Is this always true? Why is it always true?" Such questions might lead to further investigation of the models and connection-making between the geometric and algebraic equations, as discussed in an earlier section. Indeed, such reasoning and generalization skills are also vital for computational thinking when solving problems in complex systems.

Conclusion and future directions

In this study, we have discussed, mainly based on a review of literature, how mathematics can play a role in STEM activities in K–12 classrooms. From the perspective of content, we argue that mathematics serves as a language tool. This is because mathematical concepts help describe and represent the STEM activities and can be used to explain and interpret the identified solutions. From the perspective of process, we argue that mathematics serves as a thinking tool because mathematical reasoning is at the core of problem solving. In particular with the current complex systems, computational thinking that heavily relies on mathematics is critical. To illustrate our point of view, we have analyzed empirical studies, which indicate where mathematics can play a role in STEM activities and how mathematics can be made even more explicit. Based on the reviews of the existing literature, we have proposed three in-class specific actions, which hopefully will help make mathematics explicit in K–12 STEM classrooms.

We are cognizant that to make the above suggestions happen, there is a great need for teacher development and curriculum change. For instance, do our school curricula provide a space to make in-depth STEM integration? A science teacher may be concerned about limited class time to cover required science concepts, which may hinder the action of making mathematics explicit (Wong and Dillion, 2019). One alternative is to incorporate one carefully selected STEM lesson at the end of each unit in mathematics and science classes as an application of knowledge and development of STEM skills. Another possible alternative is to offer a STEM course beyond the individual disciplinary courses. These possible curriculum changes also propose challenges for teacher development and teacher education because STEM courses demand teachers' well-rounded expertise in both mathematics and other STEM areas. We call for future studies to continue this line of research to leverage classroom practices that will contribute to developing students' 21st century skills.

Glossary

Coloniality those social, institutional, economic and cultural structures that preserve and perpetuate forms of inequity endemic to colonialism after official geopolitical colonial status is no longer present

Critical Mathematics the study of mathematics as inherently political, cultural, and ideological, structuring what is understood as truth, knowledge, and forms of argument, with implications for social justice and equity

Ethnomathematics the recognition that forms of mathematization exist outside of the history of Western (school) mathematics, and that colonialism and coloniality have erased knowledges and practices, replacing them with a global assumption that mathematics is universal and neutral

Ethnomodelling the association between ethnomathematics and mathematical modeling that enables members of distinct cultural groups to perceive a different reality in relation to the nature of mathematical knowledge

Mathematization the process by which members of a distinct cultural group think and act mathematically in order to translate or interpret their own surroundings by applying mathematical knowledge, most notably universal abilities that all cultures and peoples use that of counting, measuring, classifying, patterning, gaming, quantifying, and modeling

Problem Posing a strategy for mathematizing in which one asks what-if-not about any attribute of a situation or initial question, in order to generate new problems to pursue

Mathematics is officially one of the STEM areas – science, technology, engineering, and ... mathematics. It is present in the acronym in its own right, yet perhaps also because it is understood as the “language of science” and routinely essential to the pursuit of the other associated disciplinary fields. Li and Schoenfeld (2019) refer to the special status of mathematics as a “gateway” to many scientific and technological fields, so that many future job opportunities and contributions to society are lost if and when students stop studying mathematics. The importance of mathematics is further touted when STEM skills are linked to national and global economic growth or competition (AIG 2013; OCS 2014). Parallel arguments worry about the state of mathematics given an expected increase in the demand for quantitative and computational literacy as this century unfolds, advocating shifts in the ways that mathematics is taught in order to “make mathematics a magnet” that attracts students to STEM fields and careers (Committee, 2018). It is in this latter perspective that it is often suggested that mathematics is more attractive when learned in ways that integrates its skills and concepts across disciplines, and learned through experiential, meaningful, and applied contexts. Such arguments, which see mathematics as foundational to STEM fields, seem to reduce the importance of mathematics as its own field of study, with its own value to individual self-determination and power to solve social problems independent of the other STEM fields. When mathematics is perceived only in terms of its foundational and gateway functions, it tends to be reduced to procedural skills and facts, and loses its potential for modeling, conceptual understanding and sense-making.

In simplest terms, STEM refers to a collection of separate subject areas, each with their own unique modes of inquiry and methods of discovery, problem-solving, and problem-posing. School curricula are often organized into four distinct sets of objectives, topics of study and pedagogic approaches; alternatively, STEM is potentially a discipline in its own right. STEM as its own stand-alone discipline is commonly criticized as idealistic, since it is claimed that few teachers have sufficient content knowledge

as well as pedagogical content knowledge across all four STEM disciplines to enact such a curriculum (Sanders, 2009; Fitzallen, 2015). Because of this sort of criticism, it is often advocated that STEM be treated as interdisciplinary, as a holistic approach that links the individual disciplines through solving problems that draw on concepts and procedures from the distinct fields in a context of teamwork and design methodology of engineering and suitable applications of technology. Alternatively, some propose a form of integration that does not begin with any of the specific STEM disciplines, but instead identifies knowledge development, synthesis and application in any one of the fields at one time or another, along with focused inquiry meant to support higher order learning, and other forms of rich tasks or applications to real world scenarios. This model of integration seeks to use each of the characteristics of any one or more of the STEM areas to support the development of characteristics, skills, concepts, and forms of inquiry in one or more of the other fields through ways of working that fit particular disciplines at any given time (Treacy and O'Donoghue, 2014).

Mathematics for STEM versus STEM for mathematics

The main question for mathematics in relationship to STEM, whether it is conceived as distinct or integrated disciplines, or as components of a curriculum, is, whether or not it serves mathematics or STEM fields to lump them together. On the one hand, as proponents of STEM note, integrated STEM programs have the potential to foster connectedness and meaningful applications of mathematics that might engage students, leading to greater levels of achievement or at least increased enrollment in mathematics and STEM studies beyond when it is required. At their best, integrated STEM programs make the mathematics and its real-world problem-solving potential both meaningful and accessible (Rennie et al., 2012). However, teachers often lament the loss of the standard mathematics curriculum when they experience the enactment of an integrated STEM program. The mathematics appears “watered down” to its most basic functions of data analysis, counting and measuring (Larson, 2017). The coherence of a mathematics learning program is commonly accused of being lost in the pursuit of STEM projects (Schmidt and Houang, 2007). The potential of mathematics as an aesthetic activity, as a world of inquiry in its own right independent of real-world applications, and as a unique stance to take upon the world, is typically absent, seemingly replaced by the design approaches of engineering, which otherwise would themselves struggle for a presence in the integrated activity; mathematics might in this sense be seen as sacrificed for the ways in which it would most successfully support the development of STEM as a new enterprise (Appelbaum, 2008; Bourdeau and Wood, 2019; Anderson et al., 2020). Furthermore, the inclusion of mathematics in STEM, associated with science, engineering and technology, is more likely to emphasize those aspects of mathematics that are shared with those approaches to knowledge than if it were clustered with, say, the arts, humanities, or social sciences (Sinclair, 2006; Kinniburgh and Byrd, 2008; Sahinkaya and Aladag, 2010; Appelbaum, 2012).

When mathematics is taken as a given necessity for STEM it is rarely questioned whether or not it serves STEM in general to include mathematics in the cluster. As described, the idea that mathematics is foundational to science, engineering and technology is taken for granted. Yet, mathematics is also constructed by common sense discourses as difficult and off-putting. In this way, the gateway function of mathematics is more of a problem to be solved than a contribution to STEM. Li and Schoenfeld (2019) propose a shift away from mathematics as processes and techniques of problem solving useful to science and engineering toward mathematics as a sense-making activity; that is, away from a body of content to be learned or processes in which to engage, toward the codification of experiences both of making sense and sense-making. They worry that much of the inductive parts of mathematics have been lost as it is swallowed up in STEM, but also celebrate the potential contributions of mathematics if it were to be “re-framed.” They also urge a shift in focus, away from classroom instruction, toward the student’s experience of the discipline; in other words, they wish for educators to spend less effort designing the best content sequences for mathematics, or the most optimal methods of making the content accessible to learners, and to exert more research and development work on the ways that educational environments provide opportunities for sense-making grounded in mathematical practices. Such a perspective echoes numerous calls for more attention to student experience (Appelbaum, 2008; Boaler, 2002), and mathematics as a humanistic and meaning-making endeavor (Brown, 1973, 2001), yet by placing these shifts in the context of mathematics and its support for STEM, it opens up a number of interesting, related issues.

Notion of learning for the sake of learning

To what extent is mathematics and/or STEM primarily utilitarian, and to what extent might they be concerned with capturing broader purposes of learning as contributing to a learner becoming more fully human, more capable of taking an ethical stance upon the world, better able to pursue learning for its own sake rather than its potential applications, as socially-constructed and historical forms that contribute to human endeavors and the stewardship of the planet?

Citizenship STEM or cultivation of professionals

To what extent is mathematics and/or STEM education aiming to support broad questions of public participation in and confidence in these subject areas for serving human and global needs, and on the other hand, to what extent is mathematics and/or STEM education primarily focused on the development and training of future scientific and technological professionals? A critical reading of contemporary STEM practices more generally proposes that common school experiences are highly successful in cultivating an

appreciation for the importance of STEM, science and engineering, perhaps even a reverence, and at the same time, an acceptance of others as wielding the STEM knowledge and skills, while the majority of the population remains incapable of truly grasping the details of the science (Beach, 1999; Appelbaum and Clark, 2001; Emdin, 2010). This is in some ways related to the seemingly universal embrace of mathematics as an essential component of an education, and to the equally unquestioned assumption that one or another version of mathematical literacy, numeracy, etc., is mandatory for a happy and meaningful life worth living, yet, the school mathematics curriculum has remained stuck in pre-20th Century content and methods through to contemporary life.

STEM and its relationship with the STEM disciplines

To what extent should STEM be understood as involving practices associated with mathematics, science, technology and engineering themselves, and, given the many different professional practices and philosophical approaches to each discipline, which should be represented in school experiences? Who would decide this, and, how would who is deciding make a difference for what is then constructed by the experiences as “STEM?” (Bybee, 2013) Why would the selections and decisions be chosen, and via what criteria? On the one hand, decisions might be made on the basis of assuming a neutrality of mathematics that ignores its history and continued function as supporting physical and symbolic violence (Davis and Hersh, 1981; O’Neil, 2016). On the other hand, decisions might be grounded in a desire to provide an induction into future professional practice, to a “scientific and engineering literacy” (Jarman and McClune, 2007; Hoisington, 2020; Leung et al., 2020), or a STEM-for-All introduction to content relevant to students’ current everyday life (Gitari, 2016; Cedere et al., 2020; Levrini et al., 2021). Those addressing these questions from the perspective of the T in STEM often feel caught between the academic and vocational arguments for the value of STEM in an educational program, yet propose that the weak disciplinary boundaries of the “technology field” provide a unique opportunity for learners to access a STEM curriculum (Bell et al., 2017).

These issues remain central to the relationship between mathematics and STEM, and in particular, can be the context for asking what STEM might contribute to mathematics, aside from the possibility of contexts for the application of mathematics. Larson (2017), then-President of the US National Council of Teachers of Mathematics, expressed the common litany that “we might neglect the full development of students’ mathematical understanding in order to integrate STEM “activities” into an already narrowly over-packed curriculum,” as well as the anxiety that “STEM education narrowly emphasizes learning mathematics for the workplace and for the scientific and technical communities.” He urged designers of curriculum to create STEM programs specifically tailored to developing the content and practices that characterize effective mathematics programs while maintaining the integrity of the mathematics. In his editorial, from his position as a mathematics educator, he welcomed STEM orchestrations of activity that could be understood as “vehicles to ensure students learn important mathematics at a deep level and are confident in their ability to use mathematics to be empowered in their own lives.”

One possible example of such an approach that enlists STEM activities in the pursuit of mathematics might be found in Romagnano’s (1994) story of a year in a grade 8 classroom, *Wrestling with Change*, in which STEM explorations provided models and metaphors for function concepts, which he believed at the time to be the primary conceptual power of mathematics that should be pursued and consolidated in the middle grades. Another is the story of students studying local geometric and architectural patterns on the Island of Chios in Greece (Stathopoulou et al., 2015), in which the informal knowledge of craftsmen became the basis of a dramatization created by the students of architects, historians, folklorists, and mathematicians; in this curriculum, STEM investigations led to a complex interrogation of the differences between local customs and abstract mathematical approaches. Orey and Rosa (2021) would describe the latter example as a school lesson that incorporated “ethnomodelling,” the association between ethnomathematics and mathematical modeling that enables members of distinct cultural groups to perceive a different reality in relation to the nature of mathematical knowledge. Given the dominant assumption that mathematics is the foundation for STEM, few further examples exist of STEM that serves as foundational for mathematics.

Ways of working as a mathematician

As noted above, mathematics educators often worry that the mathematics itself gets short shrift when it is absorbed into STEM. It tends to be subsumed within a set of practices that are predominantly organized by science processes of inquiry (e.g., question, observation, hypothesis, prediction, experiment, analysis of data, iterate based on results), or design processes aligned with engineering (e.g., identify need, research the problem, develop possible solutions, select the most promising solution, construct a prototype, communicate the design, redesign based on experience with the prototype). With this in mind, it can be useful to intentionally structure STEM activities to conform to processes that mathematicians commonly pursue. Those who study mathematicians notice at least three common options for such a set of processes: problem solving steps, generalizing and specializing, and problem posing.

Problem solving

Perhaps the most well-known and widely applied approach, popularized in the 1940s through Georg Polya’s (1945) *How to Solve It*, is both a summary of four steps or principles that can organize solutions to problems as well as a guide for teachers and other educational facilitators to coaching learners in these steps or principles. The first step is to “understand the problem,” which can be more likely to accomplish by asking oneself one or more of several questions: What are you asked to find or show? Can you restate the

problem in your own words? Is there enough information to enable a solution? The second step is to “devise a plan,” by using a strategy such as guess-&-check, making a systematic list, considering special cases, eliminating possibilities, or by using methods such as looking for a pattern, drawing a picture, using a formula or model, or by first solving a simpler problem. Third, one carries out the plan that was devised – Can those guess-&-check experiments or the collection of special cases be organized systematically? Can you add things to your picture and then search for relationships among the elements of that drawing? Etc. Finally, step four focuses on reviewing and extending the previous steps; potentially the most important step in the process, this involves asking if the answer makes sense, if the experience generates new questions or problems, if you would now take a different tack now that you can look back on what you did, and how you might predict a good strategy for certain problems in the future.

Using the Problem Solving approach, an educator would model the use of the processes and a creative use of the associated questions, through thinking aloud while solving problems in front of learners, and by prompting students to move through the principles when it could be helpful, until they are able to flow through all four steps on their own. Some teachers teach the steps directly, and remind the students to think about where they are in the sequence as they work.

Generalizing and specializing to generate and test conjectures

Sometimes understood as one of Polya’s heuristic techniques, the pursuit of conjectures and efforts to test them and to turn that experience into a convincing argument for the conjecture is in its own right a set of strategies and skills common to mathematical ways of working. An excellent resource for this approach is [Mason et al. \(1982/2010\)](#) *Thinking Mathematically*. This approach shares some characteristics with observational sciences such as field biology or astronomy, where one can collect data but cannot insert interventions. The mathematician collects special cases and organizes results to create categories base on attributes or outcomes. For example, one might explore a situation with small numbers, large numbers, even and odd numbers, primes, and so on; or one might try out different shapes to see how they affect outcomes, two-dimensional, three-dimensional, multi-dimensional. Once one can see patterns in the categories or outcomes, it is possible to formulate a conjecture about the situation; this generalization’ is a potential finding. Further testing of the conjecture might lead to a re-articulation of the basic requirements of the situation, if some special cases do not fit the expectations of the conjecture. Refinement of the conjecture and further testing can lead the mathematician to first convince themselves of the validity of their conjecture, and then to compose a demonstration or argument for a more skeptical audience.

This way of working would reorient some STEM activities away from the specifically utilitarian expectation that STEM solves problems and offers practical applications, toward a more conceptual interest in knowledge building and the re-framing of what is important to know about a situation. It also enables educators to harness reflection on the interaction with mathematical thinking to support learning mathematics and its STEM friends of science, technology and engineering. [Mason et al., \(1982/2010\)](#) report that skillful mathematical thinking can be improved by tacking questions conscientiously, reflecting on that experience, linking feelings with action, studying the process of resolving problems, and noticing how what is learned fits with the experience. They also note the importance of spending time on recalcitrant questions that resist resolution, and have found that answers to questions or solutions to problems are not as important as the experiences of working with the methods of thinking and organizing mathematical activity. With this in mind, it is critical to see that the most powerful mathematical experiences often should be untangled from practical applications and a solutions-fixated problem-solving or design-structured experience. One STEM curriculum strategy is to pursue this in parallel with the S- or E- grounded situation, isolating the mathematics that was used for further, independent explorations.

Problem posing

A seemingly neglected potential contribution of mathematics to STEM learning and practices is the art of problem posing that is at the heart of mathematics ([Brown and Walter 1983/2004](#)). This specifically mathematical collection of techniques for composing new and original questions could transform STEM, which tends to seek designed solutions to given problems, into the practice of re-thinking what the problems might be in the first place. Even if one prioritizes learners’ eventual ability to solve problems, Stephen [Brown \(2001\)](#) points out that the skills of problem solving and mathematical concepts and techniques that would be applied to solve problems might more readily be learned and assimilated through activities other than solving problems. This insight is akin to a sports coach who notes that there may be valuable ways to develop and refine skills and concepts other than playing the sport over and over again – exercises, isolating body awareness and so on. In the context of mathematics and STEM, problems might be compared, changed, critiqued, and so on, instead of trying to solve them. Each of these alternatives would help learners to better approach problems in the future. Certainly, the experience of critiquing given problems, seeking to understand who posed them and why, and altering problem statements is an issue of ethics: learners should not be acculturated into assuming that only others pose problems, and instead should be mentored to see themselves as contributing a critical stance on problems as citizen mathematicians and scientists.

Problem posing itself can begin with given problems. One then asks, “what if not?” about any attribute or attributes of the initial problem. Once one has done this a few times, a mathematician can see the original problem as only one very special case of a family of limitless variations on a collection of elements and relationships. To take a somewhat simple example, suppose the initial problem asks about a family with 3 adults, 1 child, and 1 1-month-old baby boarding a public transportation system. An initial question might ask how much the ride will cost, given prices of tickets. A first what-if-not transformation could ask how the total cost

would change if the ticket prices changed to other amounts; a next step in the process could ask about further changes in ticket prices. Further posing changes might ask, “why do cities charge at all for public transportation ... might the costs be different if the service were “free to ride,” reducing use of roads, bridges, and other forms of transportation? Or: why does this family need to travel all together ... where are they going, and how would their costs be different if public policies did not require them to appear in person at the government agency? Such an approach drastically alters the initial problem statement, challenges the view that STEM solves problems by making it clear that STEM can also critique social assumptions, and more.

Different kinds of models for different sorts of purposes

Independent of the approach to working as a mathematician, mathematicians often vary in the purposes of their models and representations. When STEM is guided primarily by science processes, then the models are typically used to create a representation of the relevant relationships in a system. The model represents objects, phenomena, and physical processes in a consistent and logical way, and enables the scientist to develop scientific understanding by seeing how a change in one aspect of the model would influence changes in other components. Historically important models include the billiard ball model of a gas, the Bohr model of the atom, the Lotka-Volterra model of predator-prey interaction, the Mundell-Fleming model of an open economy. Engineering models tend to be created so that the engineer can assess the advantages and disadvantages of a design architecture, using indices or criteria to compare one model with another in terms of desired outcome measures. Engineers need to consider formal versus informal models, physical versus abstract models, descriptive models, analytic models, and so on. Different kinds of models are more or less appropriate at different stages of a design process; often, the models are employed to explain to a client or audience why they should support or fund the engineer’s proposed plan of action. Mathematicians might use models for similar purposes, as they build a subfield of knowledge or attempt to convince a skeptic of the logic of a conjecture.

Yet, there is a third use of models less tied to science and engineering design, in which a mathematician creates a model for problem-posing purposes, that is, to generate questions rather than answers or solutions. What can we learn about fractions if we use an area model instead of a linear model? What can we learn about triangles if we place them on a globe instead of on a flat two-dimensional plane? How do our questions about circles and ellipses change if we look at them algebraically instead of geometrically? Learners who are lucky enough to have experiences with these kinds of activities not only develop skills of solving problems with and through the use of models, but furthermore develop a sensibility that appreciates the ways that a particular model can limit or hide alternative realities and possibly more important questions. [Brown \(2001, p. 2\)](#) asks,

Have you thought ... of designing car bumpers that make use of liquid or that are magnetized, or shaped like a football? The creation of air bags suggests yet another option ... that bumpers might be capable of inflation on impact. Or, have you thought of the possibility that they may be made of glass, the fragility of which might discourage people from driving recklessly or relying so heavily on the use of the automobile?

He further stresses a feature of “coming to know” that such playful and initially less practical uses of models can encourage: in order to move from learning as being guided by an authority toward understanding oneself as a creator of knowledge, it is important to operate upon and even modify the things we are trying to understand. Ironically, it is often only in seeing a thing as something else that we can come to appreciate and understand it. Considering how one’s choices of models can affect the questions one poses as well as being more or less accessible to an audience with whom one is attempting to communicate has yet further implications: the perspectives of different groups in society are often neglected by the inclusion or loss of information in a model.

Social justice, mathematics and STEM

Not only is mathematics often blamed for discouraging people from pursuing STEM studies and careers, it is also then held responsible for disparities in STEM interest and STEM literacy cutting across racial, gender and socioeconomic lines. It is a consistent narrative that the vast majority of students being filtered out of mathematics, and subsequently, out of STEM – i.e., those whose experiences with school mathematics have led to disengagement as they learn to believe that they “can’t do math” – are more often underprivileged, underserved, and underrepresented ([Cherkowski, 2019](#)). While it is mostly the methods and biases of typical mathematics classrooms that are at fault more than the subject matter itself, mathematics will continue to be charged with the perpetuation of social and economic stratification, divisiveness, and cultural inequity unless practices are changed. Mathematics – and, if the gatekeeping function for STEM continues to be associated with the school subject, then STEM as well, will remain linked to social justice inequities in vocational and educational opportunities, earning potential over a lifetime, emotional and social well-being, volunteerism, and job satisfaction ([OCS, 2014](#); [Committee, 2018](#); [Cherkowski, 2019](#); [Block, 2020](#)). Furthermore, cultural, ethnic and gender diversity is linked to higher innovation outcomes, a key driver of STEM progress; research further reports that ethnically diverse workforces financially outperform non-diverse workforces by 35%, and a gender diverse workforce yields a 15% increase in financial output ([Desvaux et al., 2007](#); [Block, 2020](#)). In this way, STEM, and particularly mathematics for STEM, is a social justice issue in two ways: first, in terms of how mathematics and STEM education and apprenticeship practices support increased participation, and in particular, to find creative ways to remove any barriers to opportunity; second, policy

and practice must consciously avoid “blaming” members of disadvantaged, underserved and underrepresented groups for not adequately participating in STEM programs or pursuing STEM careers – the latter would be a dangerous and reprehensible treatment of human beings as resources to be mined for economic and intellectual progress. As Block (2020, p.27) notes,

Black students’ disproportionate interest in social justice and the absence of Black STEM majors are causally related. In their courses and jobs, most STEM faculty and employers do not make social change a focus. And for many Black students, that’s a serious problem.

Black students in particular often seek university majors in disciplines associated with public service despite dim salary prospects of careers with explicit social justice orientations (Block, 2020). Yet, studies of equally prepared Black, Latino and white students from similar financial backgrounds who started out their university studies in STEM fields found that Black and Latino students were 14% points more likely to leave STEM programs, a pattern not replicated in non-STEM fields of study (Block, 2020). Although many researchers point to the lack of diversity in STEM faculty, more powerful seems to be the STEM community itself: surveys suggest that STEM programs and early career opportunities overwhelmingly focus on technical expertise and the solution of given problems. “The people who are in most STEM programs and run most STEM organizations are not from those same backgrounds and do not have those same kinds of concerns,” leading many Black students to feel lost or unwelcome, reported one interviewee in Daniel Block’s (2020) article.

Given the plethora of socially conscious and diverse STEM crises and problems needing solutions in our world, the potential for STEM productivity in such areas to reap good profits should be apparent to even the most money-focused and technique-driven STEM professionals. Opportunities for transportation not reliant on fossil fuels, new sources of energy, methods of contending with climate change, health issues related to climate, weather, and other contexts, new forms of medicine, skin care and cosmetics, ...the possibilities seem endless. Related to the ways of working, models, and the ethics of problem solving and posing, it is an important social justice issue to make sure that STEM experiences include those characteristics of mathematical practices that emphasize multiple perspectives on problems, challenging assumptions that guide work, and directly understanding the social justice implications of the STEM projects themselves. In this sense, it is critical to include forms of problem posing and modeling that critique given problems in certain ways, including:

- Who was not included in the framing of the question?
- Does this need remain a priority when compared with other possible foci of our energy, given the competing needs of a diverse community?
- What questions are generated by using an alternative model, or an alternative way of working, shifting among science processes, engineering design steps, and ways of working as a mathematician?

And,

- What are the social justice implications of this project and its potential solutions?
- What social justice questions should we be working on in this program?

Although many issues of global and local importance such as climate and associated weather change, mass migration and refugee flow, homelessness, starvation and more appear to require critical perspectives across multiple disciplines, and overlap with STEM opportunities, it is often proposed that critical mathematics education can introduce specifically mathematics problems that establish the STEM and social justice linkages (Garibay, 2018; Nicol et al., 2019). Attempts to make this work find that it is the creative dialogue across discipline experts that can support the inclusion of cultural perspectives, diverse experiences and expertise, highlighting the need for those who would want to pursue this sort of work to understand that there are more options for integration than those that maintain disciplinary boundaries (Ortiz-Revilla et al., 2020).

Cross-cutting concepts and mathematizing

Science and engineering practices provide actions by which students gather data and information, whereas cross-cutting concepts provide techniques for students to process and think about the data and information (NRC, 2012; Cooper et al., 2015). Some common cross-cutting concepts rely on mathematical thinking and action to link the different domains of science and engineering. Patterns, scale, proportion, quantity, systems and system models, structure and function, and stability and change each have this characteristic; energy and matter as a cross-cutting concept would seemingly work in the opposing direction, that is, primarily using mathematics to support a science and engineering concept. Participation in such practices helps learners to form a holistic understanding of the cross-cutting concepts and the ways that they take on specific characteristics when viewed within one discipline or another. In theory, the concepts would make students’ developing knowledge more meaningful and would embed the practices relying upon the concepts more deeply into their worldview. The M in STEM offers a rich and powerful set of additional cross-cutting concepts and practices through mathematizing: “the process [es] by which members of a distinct cultural group think and act mathematically in order to translate or interpret their own surroundings by applying mathematical knowledge, most notably universal abilities that all cultures and peoples use: that

of counting, measuring, classifying, patterning, gaming, quantifying, and modeling” (Orey and Rosa, 2021). When we pull these processes out of the science and engineering practices, to analyze in their own right, and to reflect on the choices for how to accomplish them, what they leave out, when and how they influence our questions and conclusions, and so on, we can bring them back into the STEM activities with a significant understanding of both their power and limitations.

The field of critical mathematics education has a history of exploring such power and limitations that can benefit STEM programs if the wisdom can be more fully integrated (Ernest et al., 2016; Stathopoulou and Appelbaum, 2016; Nicol et al., 2019). The important point to be gained from this perspective on mathematics is that, while traditionally assumed to be the most neutral of all disciplines, and the furthest removed from politics, culture and ideology, a more critical stance clarifies the ways in which mathematics can and has structured and filtered social and cultural conceptions of truth, fact, knowledge, forms of argument, and more. One example of the ideological and political nature of mathematics is the ways that the discipline has provided knowledge and methods for colonial powers to create hierarchical systems and institutions. Even further, the last century of ethnomathematics has established the role of mathematics and mathematical problem solving in preserving and perpetuating inequities and injustices of colonialism well after official geopolitical status is no longer present; this situation is known as “coloniality,” and is often associated with the erasure of indigenous forms of mathematizing found outside of Western historical understanding, within colonialism and coloniality itself (Stathopoulou and Appelbaum, 2016; Appelbaum and Stathopoulou, 2020). Once the ideological and cultural constraints and formatting power of mathematics is recognized, next steps include action within mathematics and mathematics education to move toward a broader sense of responsibility and social justice (Appelbaum and Stathopoulou, 2020). One can also carry out similar ethnoscience and ethnoengineering projects, as well as ethno-STEM pursuits. Any attempt to presume STEM has a neutral or mostly positive role in solving problems ignores the hidden colonialism and loss of alternative epistemologies that STEM carries with it when left unchecked.

We might say that world civilization, far beyond STEM, is anchored in mathematics as its dorsal spine (D’Ambrosio, 2016). Yet, mathematicians often claim that their subtlest thinking is beyond comprehension of those seated around the table attempting to solve the most pressing issues of survival, social justice, and human dignity. This is a failure to tackle the challenges of packing and unpacking complexity in order to render it comprehensible with loss of relationships vital to the more complex patterns. They have further ignored the potential of forms of mathematizing that are not visible if only recognized when they match existing, Western forms of mathematizing, so that such potentially essential methods of thinking and being for solving questions of survival and human dignity would be available in our world. Extending this critical stance to STEM, we see the need for STEM practices and action to incorporate an analogous perspective that asks what coloniality has made invisible. This pursuit should begin with critical ethnomathematics, simply because the mathematics typically included as the M in STEM is so commonly treated as a neutral set of tools for solving problems articulated in terms of science or engineering. However, the next steps must take techniques and principles from critical ethnomathematics into the STEM work: understanding both mathematics and the STEM fields in general as inherently political, cultural, ideological, and historically situated – the more nuanced and essential lesson to be contributed by mathematics as a discipline, rather than as a collection of tools – is the opening to a far more exciting version of STEM, perhaps termed “critical-ethno-STEM.”

Introduction

The early years of the 21st century yielded a growing interest in engineering education research (Sheppard et al., 2009; The Steering Committee of the National Engineering Education Research Colloquies, 2006). Worldwide, many institutions established graduate programs, research centers, and global collaboration networks in engineering education (Clark, 2011; Gumaelius and Kolmos, 2019; Yasuhara, 2021). The National Academy of Engineering in the United States published two influential reports. *The Engineer of 2020: Visions of Engineering in the New Century* envisioned the future of engineering education followed by another report which explained how educators should prepare for that future (NAE, 2004, 2005). While the early reports focused on undergraduate and graduate education, pre-college education was also targeted with recommendations to support K-12 mathematics, science, and engineering education and the need to promote public understanding of engineering. In later years, engineering education in pre-college education continued to gain momentum. This article reviews these developments and provides frameworks and strategies necessary to guide pre-college engineering education.

Engineering in pre-college education

The importance of pre-college engineering is often positioned under the umbrella of science, technology, engineering, and mathematics (STEM) education. In particular, engineering design is typically described as an approach to engage students in real-world design problems that necessitate the integration of science, mathematics, and technology. Given this definition, the STEM movement lead to a variety of curricular models. For example, other subjects are added to the STEM acronym by including the arts (STEAM) or computational thinking with STEM + CT. In other cases, robotics and maker spaces emerged as signature activities of the STEM model.

This variety can be attributed to different factors. First, the interdisciplinary nature of STEM resulted in differences in teaching models as scholars from different disciplines approach integration differently. Such variation can be explained with a disciplinary perspective that can be attributed to the epistemological stances of the scholars. For example, how scientists use and integrate technology, mathematics, and engineering in their work differs from how engineers use and integrate technology, mathematics, and science in their work. Such variation is different than the variation attributed to pedagogical differences. Second, the STEM movement emerged with a diverse set of motivations ranging from helping students gain a deeper understanding of science and mathematics concepts to growing a more diverse engineering workforce to promoting creativity. Yet, the body of literature has shown that accomplishing these benefits has not proved to be easy (Valtorta and Berland, 2015). In addition, the novelty of the STEM education movement resulted in variation of interpretations and hence variations in quality. Scholars concerned over this variation developed frameworks to guide curriculum quality (Moore et al., 2015) and comprehensively define dimensions of engineering (AE3 and ASEE, 2020). Given these factors, the vast variation in STEM education is inevitable.

In our prior work, we argued that it is beneficial to integrate engineering into formal K-12 education, but the implicit argumentative stances of the educators, who design the educational experience, must be made clear (Purzer and Quintana-Cifuentes, 2019). The value attributed to engineering design can be pedagogical, epistemological, or methodological. The pedagogical argument treats engineering and design as vehicles for motivation to learn science and mathematics concepts. For example, a lesson where students are engaged in a series of thermal transport experiments, asked to design an insulated container, and assessed on their understanding of thermal concepts is built on a pedagogical perspective. The methodological perspective puts value in skills acquisition making design the vehicle for learning collaboration, creativity, and problem solving as well as habits of mind such as comfort with failure. For example, a lesson where students are asked to follow a design process using a limited amount of materials to build a strong structure, which is tested for strength but without explicit discussion of material strengths, and assessed on their design and communication skills, is built on a methodological perspective. The epistemological argument centers on the inherently interdisciplinary nature of engineering but also positions that the pedagogical decisions must be justified with a philosophical

grounding. For example, a lesson where students are re-designing their school building to improve its energy efficiency under specified economic and structural constraints, and expected to learn about thermal concepts, earth science concepts, as well as trade-off decisions involved when designing, is built on an epistemological perspective. Understanding the specific argumentative stances helps explain variations in curriculum.

While we highlight the importance of each of these argumentative stances, we also caution educators and researchers against a monolithic approach. We argue that the epistemological perspective can most effectively guide a variety of models given the multifaceted nature of engineering. The following sections provide guidance for shaping pre-college engineering with an epistemological perspective.

An epistemology-based framework

Engineering is inherently interdisciplinary. Hence, the pedagogical role imposed on engineering as the integrator of school subjects is justified. However, simply making this connection is not sufficient. Many curricular efforts fall short of a further examination of the engineering profession, such as the necessity for making design judgments in context.

Often engineering is defined by its practice, which is design. However, to understand engineering, we must first articulate its purpose and motives. Purzer et al. (2022) defines the purpose of engineering as “the creation, monitoring, management, and improvement of technological systems through the careful negotiation of risks and benefits” (p. 8). This definition recognizes the purpose of creating new technologies but also the critical role of engineers in maintaining the existing technologies. This definition also argues that engineers engage in different types of inquiries. At the core of the practices that guide these inquiries is communication and negotiation and the need to satisfy clients or stakeholders and convince them of the quality of the design decisions. This approach resulted in the Honeycomb of Engineering framework, designed based on the principle of engineering as a socially-constructed process and the design process as the flexible, iterative, and adoptable guide for engineering (Purzer et al., 2022). The Honeycomb of Engineering takes an epistemological perspective to outline an ontological classification of six types of engineering inquiries:

1. User-centered design
2. Design-build-test
3. Engineering science
4. Engineering optimization
5. Engineering analysis
6. Reverse engineering

The flexible nature of the design process is adapted to guide different inquiries by highlighting key cells of the honeycomb. In pursuing these inquiries, relevant elements of engineering design are used while maintaining the common core practice of negotiation of risks and benefits. With a honeycomb representation, illustrated in Fig. 1, this framework positions the negotiation of risks and benefits at the center of the design process and enables iteration through communication and reflection (Purzer, 2021).

While an epistemologically-justified framework helps to guide and delineate design projects, it also helps clarify a loosely used descriptor attributed to curriculum: authenticity. A commonly used attribute of the design challenges is their authenticity—meaning the degree to which they represent real-world design projects (Garrett et al., 2016; Strobel et al., 2013). In a prior study we provided comparisons of two curricula in ways they emphasize or de-emphasize different authenticity aspects (Schmidt et al., 2021). We argue that vague references to authenticity that deviate from disciplinary epistemic practices have risks such as: student motivation will be lost; the learning outcomes will be weakened; and inaccurate perceptions of engineering will develop. These risks run counter to the aforementioned elements that bring engineering to the forefront of educational reform. Hence, there is much we can lose if authenticity is not planned into the design of curricula.

Authenticity and inclusiveness in engineering curriculum

The epistemological perspective into engineering education brings with it the elements of authenticity. For example, context authenticity defines lessons and design projects that take place in contexts similar to those in real-world contexts (Strobel et al., 2013). However, these descriptions require clarification of the terms such as “real-life” and “authentic” which are commonly used in reference to engineering curricula. Having authentic features is important for a lesson to be engaging. Yet, haphazardly labeling curricula or engineering lessons as authentic can also result in misrepresentations. Strobel and colleagues provide clear definitions of authenticity by distinguishing context authenticity, task authenticity, impact authenticity, and personal authenticity.

Projects with context authenticity embed problems in realistic contexts while promoting interdisciplinary problem solving and collaboration. Projects with task authenticity focus on ensuring specific tasks within a lesson are domain-relevant and reflects tasks that are practiced by engineers. Context and task authenticity deal mainly with the alignment of curriculum elements with the epistemic practices.

Fig. 1 The Honeycomb of Engineering (Purzer, 2021).

There are also types of authenticity that influence motivation to learn but also support inclusive education. For example, impact authenticity connects curricular elements with issues that expand beyond the classroom or school. These types of lessons can encourage decision-making and community-wide discourse around societal concerns or events. Personal authenticity, on the other hand, is designed around students and their daily life. Such lessons are designed with an understanding of students' interests, assets, and agency and aim to make explicit connections between school and aspects of students' everyday lives. Without personal authenticity, engineering lessons risk the loss of relevance for students. According to McGowan and Bell (2020) efforts to promote engineering in K-12 education continues to perpetuate stereotypical notions of engineering with old narratives that are not inclusive of women and individuals from underrepresented groups. They argue that engineering projects that connect to students' everyday experiences allow inclusive education and the opportunity for educators to build on to the students' assets.

Creating engineering curricula, especially with authenticity, requires decisions that are practical, epistemological, and pedagogical. For example, decisions must be made in terms of authenticity vs. accessibility, simplicity vs. disciplinary depth, etc. These decisions must be made explicit along with contextual constraints (such as school resources) and trade-offs that have to be made.

Design coaching and responsive teaching

Similar to how taking an epistemological perspective helps curriculum design and evaluation and ensures authenticity, such a perspective can also help frame teacher education. To establish this link, we can simply ask how design is taught in higher education. Adams et al. (2016) argue for the critical practice of coaching in design education. In their study of experienced design educators across multiple design disciplines, they identified four common coaching practices (Adams et al., 2016):

- eliciting student articulation of reasoning by directing students to share their design solutions and plans,
- helping students make conceptual connections and recognize fallacies in their design decisions,

- conveying explicit knowledge associated with design strategies and expert habits of mind, and
- encouraging students to figure out their own results by suggesting that they test the outcomes themselves and reflect on the results.

In design education, this type of teaching is called design coaching (Adams and Siddiqui, 2016). In educational research, design coaching can best be explained with the adaptive and responsive teaching model (Sherin et al., 2011; Johnson et al., 2017). Hence, through design coaching with responsive teaching, teachers can adopt strategies that facilitate student reasoning such as: noticing student reasoning, responding to student thinking, and helping student thinking evolve. Teaching engineering in such a manner that reflects authentic practices is undoubtedly a demanding task. Yet, effective teachers frequently and skillfully attend to aspects of student needs that are cognitive, emotional, and behavioral. Such attention then translates into instructional decisions such as responding to students' misconceptions, intervening to resolve social conflicts, and making revisions to classroom management (Dalvi and Wendell, 2017).

Teachers' competencies in design coaching would develop over time. To scaffold this development, educators can be provided with tools and strategies to notice and elicit student thinking, interpret student thinking, and respond to such thinking. Teachers can facilitate this through the Engineering Design Coaching Tool (Purzer et al., 2021). This instructional tool is designed to help educators elicit student reasoning through guided questioning. This questioning then helps students verbalize their thinking processes, share evidence in support of their decision, notice fallacies in their thinking and guide design decisions—hence stimulating student learning.

Another way to promote pre-college engineering education is by building on design practices in which educators already excel. According to Wendell, idea generation and feasibility analysis of potential solutions were strong assets of pre-service teachers when they engaged in engineering design (Wendell, 2014; McCormick et al., 2014; Moore et al., 2015). Conversely, these teachers were not as proficient in problem scoping. This finding helps explain results from our prior analysis with the finding that design-build-test projects were prominently common at all levels of education across primary and secondary school (Purzer et al., 2022). Design-build-test inquiries used in engineering practice emphasize ideation and feasibility analysis. Moreover, design-build-test problems entail clear design criteria and constraints and do not require in-depth problem scoping. In another study, Judson et al. (2016) analyzed middle school teachers' lesson plans in engineering and found data analysis and design comparisons were strengths of the teachers. This finding points to an opportunity suggesting that teachers may enjoy and excel in developing and teaching engineering analysis and optimization projects. Yet, these types of lessons were uncommon in our analysis, together making up only 3% of the lessons we analyzed. Hence, it is important that teacher education and professional development efforts introduce educators to the variety of inquiries used in engineering practice and ways these practices can be translated to education. In such, teachers are empowered by recognizing their assets and strengths and gradually build their competencies in coaching engineering design projects. These efforts would then translate into improved student learning and abilities in engineering design reasoning.

A focus on engineering design reasoning

Striving for responsive teaching in the context of authentic design projects requires a clear definition of what reasoning entails for the discipline of engineering. There are two important elements of engineering reasoning. One entails the ability to transition between concrete and abstract modes of thinking. The second entails the ability to think deeply within disciplinary ideas as well as broadly across multiple disciplines. At the intersection of these two spectrums of reasoning is the Quadrants of Design Reasoning with the following four elements: experiential observations, first-principles, trade-offs, and complex abstractions (See Fig. 2).

Experiential observations refer to reasoning at the concrete level with elements of procedural actions, trial and error processes, and everyday experiences. The *first-principles reasoning* refers to the applications of science and mathematics as well as principles from other disciplines such as economics, psychology, and arts. These foundational principles, which we label as first-principles, are indicators of theoretical support for design decisions. *Trade-offs* require crossing disciplinary boundaries to weigh and negotiate multiple design criteria. Reasoning with *complex abstractions* requires imagining how a solution might behave in other conditions beyond the current context or situation. Together the four modes of reasoning and the ability to fluently transition across them is essential when designing.

Some critiques of STEM education argue that the resources allocated to STEM education take away from liberal arts and civic education. However, if done properly, engineering design education would include disciplinary concepts such as ethics. Therefore, we have chosen the label, first-principles, as opposed to narrowly defining it as science and mathematics. Trade-offs are also important to consider when examining ethical issues. For example, safety is of vital importance in engineering, as well as values such as fairness and diversity. First-principles reasoning allows for deeper exploration of such disciplinary concepts. Trade-offs reasoning will also help student designers explore the intersection between the technical design requirements and the ethical design requirements. For example, designing a virus testing kit with high accuracy may limit its broad accessibility due to its high cost. Complex abstractions allow designers to imagine their products in the future so they can avoid unintended consequences. Hence, a focus on engineering reasoning in education would support learning across all school subjects and not just in STEM subjects.

Fig. 2 Four dimensions of engineering design reasoning.

Conclusions

As education systems recognize the importance of teaching engineering in pre-college education, it is important to articulate the practices and philosophical underpinnings of the discipline of engineering. Studies of the philosophy of engineering help provide guidance. This article outlines six engineering inquiries: design-build-test, user-centered design, engineering science, engineering optimization, engineering analysis, and reverse engineering. With an understanding of different inquiries informed by the engineering philosophy, we can design curricula that enable authentic projects, engaging learning, and inclusive education.

Teaching engineering in ways that authentically reflect the engineering practice is aligned with the responsive teaching model which promotes the important practices of teaching such as guiding student ideas, responding to students' needs, recognizing creative ideas, and noticing misconceptions. Hence this article equates the role of the teacher with the role of a design coach and presents frameworks and strategies to guide pre-college engineering education. Teaching engineering in authentic ways also supports inclusive education. Design projects with impact and personal authenticity allows educators to build connections between engineering and students' everyday life and build on their assets and lived experiences. Such problem solving at the intersection of technical knowledge and lived experiences support student learning through authentic design. This article argues for a careful examination of pre-college curriculum and practices in engineering, so we can design curriculum that enable inclusive education.

Engineering education provides wide learning opportunities and will continue its momentum and expansion in pre-college education. For this movement to lead to improved student learning and engagement, authentic engineering curricula must be taught through responsive teaching and design coaching. These efforts would have the biggest impact on pre-college education when the learning outcomes goes beyond content knowledge in science, technology, engineering, and mathematics but include evidence-based and ethical decision-making as well as the ability to develop creative solutions to real-world problems.

Introduction

Language has long been considered to play an essential role in science education and science literacy, with its epistemic affordances for both communicating and constructing knowledge and understanding. More recently, the role of language in science, technology, engineering, and mathematics (STEM) education and in STEM literacy development have become areas of interest for educators and researchers. STEM education has been defined by various stakeholders in different ways. For some educators, an activity focusing on any one of the four STEM disciplines would be considered a STEM learning experience; however, for most educators a true STEM learning experience involves some integration of multiple STEM disciplines. Proponents of this integrated definition range from requiring STEM education to involve a combination of any two of the disciplines, to requiring all four disciplines to be meaningfully and purposefully integrated in a single learning experience in order for true STEM education to be attained. Although debate over what constitutes the most appropriate definitions of STEM and STEM education is ongoing, our perspective is that STEM learning experiences require authentic integration between and among two or more STEM disciplines. In fact, we assert that a critical attribute of effective STEM education is disciplinary integration because of the epistemic similarities between an integrated view of STEM and the multimodal nature of the language used to communicate and construct meaning in STEM.

Here, we present our views on the multimodality of language as we explore various perspectives of literacy, including language and literacy; disciplinary literacy; individual science, technology, engineering, and mathematics literacies; and STEM literacy. We identify the multimodal affordances of language as a commonality across these perspectives and discuss three models of multimodality that can be used to consider the role of language in STEM. We describe the possibilities inherent in language-rich STEM learning experiences and propose that STEM education can be a springboard to enhanced development of language and literacy skills. Drawing on the affordances of multimodalities, learners' language and literacy skills can be developed while STEM concepts are explored, simultaneously strengthening both communication skills and STEM understanding. Language-rich integrated STEM can then be considered as an avenue for enhancing language and literacy, as well as aspects of science, technology, engineering, and mathematics literacies, rather than as a content area that draws time away from an already full curriculum.

What is language and literacy?

Literacy describes mastery of particular skills and abilities within a particular context. In the context of language, literacy once meant proficiency in reading and writing, the only two recognized strands of language. However, in response to sociopolitical changes, the conception of literacy broadened to incorporate the strands of listening and speaking. More recently, advances in communication technologies led to the complex notion of multiple literacies that encompassed static and dynamic images as well as words and sign systems. In response, the strands of viewing and representing became acknowledged as important aspects of language.

These six strands – reading, writing, listening, speaking, viewing, and representing – represent our current framework for understanding of language and literacy, although they are sometimes presented in different combinations; for example, as reading,

writing, oracy, and media literacy; or with reading and writing encompassing viewing and representing respectively. The strands of language can also be classified by function, as shown in Fig. 1. Reading, listening, and viewing can be thought of as interpretive strands, while writing, speaking, and representing can be thought of as constructive strands. These strands interact during both the construction and communication of knowledge.

The emphasis of the interpretive strands is on making sense of preestablished information, while the emphasis of the constructive strands is on using language to generate and clarify understanding and subsequently to communicate that understanding. An emphasis on inquiry based and constructivist approaches to teaching STEM means that the constructive strands are receiving growing attention. There has been a shift toward learning *with* language, rather than learning *from* language, as researchers and educators recognize the importance of all six strands – and their interactions – in communicative, constructive, and argumentative aspects of disciplinary literacy.

Disciplinary literacy

Disciplinary literacy includes using a range of representational modes (e.g., written and oral language, images, music, and gestures) to construct and communicate information, to synthesize ideas, and to formulate arguments (Moje, 2008). Just as science literacy encompasses specific ways of reading, writing, listening, speaking, viewing, and representing that are culturally mediated in the discourse of science, STEM literacy entails reading, writing, listening, speaking, viewing, and representing in ways that are particular to the discourse(s) of STEM. A useful conceptualization of disciplinary literacy differentiates among basic, intermediate, and disciplinary literacy skills and practices (Shanahan and Shanahan, 2008). Basic literacy practices are the highly generalizable practices that most students would be engaged in during the primary grades. Intermediate literacy practices, which are neither generic nor specific to a particular discipline but are more broadly useful depending upon context, are typically acquired during the intermediate grades. Disciplinary literacy practices, which tend to be highly sophisticated and not widely generalizable, reflect the discipline within which students are constructing meaning and are typically acquired during high school and university. These three clusters of literacy skills and practices are shown in Fig. 2.

In Fig. 2, each step in the progression of disciplinary literacy becomes smaller, reflecting a more limited generalizability of the practices, and the height of the steps reflects the level of specificity of the practices. Learning requires movement up and down the steps as new literacy practices are developed while other practices that have already been mastered are utilized. Also, mastery of a specific practice in one stage does not mean mastery of all practices in that stage. It is important to note that disciplinary-specific language is shaped by the specialized demands of communicating disciplinary concepts. For example, in science, the construal of scientific meaning has led to unique grammatical and textual features such as high lexical density, abstraction, and technicality, as well as the frequent use of visual representations. The presence of multiple visual representations and symbolic language means that the discourse of science is multimodal, and by association, we would argue, so is the discourse of STEM. An emphasis on the use of representations in STEM is a critical and more sophisticated aspect of disciplinary literacy that would emerge as a focus in the intermediate grades and continue into high school and university.

STEM literacy

As science education researchers, we can identify clear alignment between science and STEM, and between science literacy and STEM literacy. However, we acknowledge science is just one of the four traditional disciplines of STEM, along with technology,

Fig. 1 The six interactive strands of language. Adapted from Tippet (2016, p. 727).

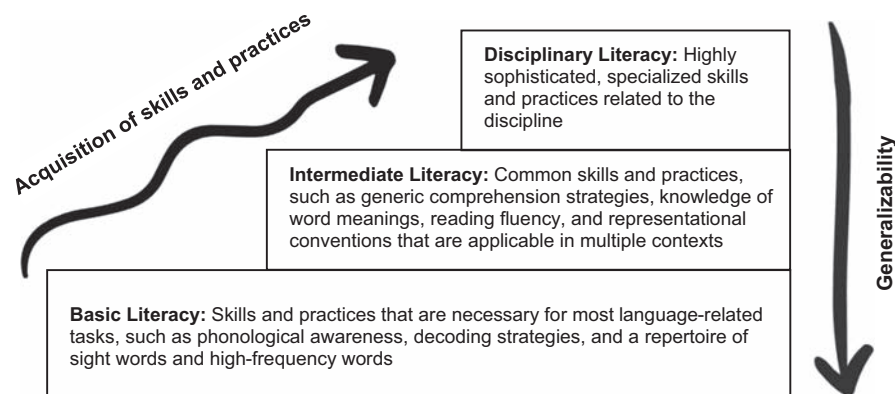

Fig. 2 Disciplinary literacy development. Adapted from [Shanahan and Shanahan \(2008\)](#).

engineering, and mathematics. We also recognize that integrated STEM experiences can provide broader and more general opportunities for the acquisition of science concepts and disciplinary skills, as well as for the development of technological and engineering literacy, numeracy, and language and literacy practices. Although there is some debate as to whether educators should be targeting an integrated STEM literacy or considering the literacies of the four individual S-T-E-M disciplines, the idea of a disciplinary literacy – particularly as proposed by [Shanahan and Shanahan \(2008\)](#) – is widely accepted ([Mohr-Schroeder et al., 2020](#); [Tang and Williams, 2019](#)). Situating STEM as a discipline in its own right, and building on the idea that the whole of STEM is greater than the sum of its parts, still calls for the simultaneous use of knowledge, skills, and practices from all four STEM disciplines. Our perspective is that even an integrated STEM literacy must consider the commonalities and differences of each of the four constituent disciplines. Here, we present an overview of conceptions of literacy within each discipline followed by a discussion of the commonalities that we, and other researchers, have identified.

Science literacy

Of the individual STEM disciplines, science has perhaps been the most studied, and current conceptions of science literacy are nuanced. [Norris and Phillips \(2003\)](#), in what may be the seminal work on the central role of language in science literacy, proposed the interacting fundamental and derived senses of science literacy, with language identified as a fundamental sense. Most subsequent conceptualizations of science literacy continue to acknowledge the critical role of language arts, with language conceptualized as a multimodal means of constructing and communication science knowledge. As an example, a recent metaphor for science literacy (see [Fig. 3](#)) reflects the growing need for a population that takes an informed role in civic actions. This metaphor situates language and literacy in the fundamental dimension of science literacy and illustrates that by engaging learners in active participatory learning with an authentic civics focus, disciplinary understanding can be enhanced by the effective use of language.

As suggested in [Fig. 3](#), true science literacy involves the integration of multiple skills, attributes, tools, and understandings. For students, and for that matter all citizens, science literacy requires an understanding of the philosophical nature of the scientific discipline and of the foundational conceptual big ideas of scientific knowledge. True science literacy would also involve an understanding of the processes and tools utilized to develop those big ideas. This conceptualization of scientific literacy obviously moves beyond rote memorization of discrete facts toward application to complex, real world problems.

Technology literacy

The discipline of technology is the least well-articulated of the four STEM disciplines, with ideas about technological literacy equally under-developed. This situation, described as a pervasive problem by [Ellis et al. \(2020\)](#), is being addressed, but misconceptions and misunderstandings about the meaning and role of technology are prevalent. There is also debate about whether technology should be considered as the T in STEM, or only in combination with engineering – part of the T/E in ST/EM. In our comparison of disciplinary literacies, we consider technology separately. Further, we take a perspective on technology and technological literacy that situates technology as tools; within STEM education, technology can be considered as tools with which to engage in authentic learning aimed at exploring STEM concepts. This perspective is a more encompassing vision of technology than is sometimes proposed because it does not focus exclusively on high-tech information and communication technologies but includes low-tech “tools” often more readily accessed by students of all ages. Consider how complex scientific concepts such as dynamic equilibrium or stoichiometric relationships can best be explored using simple tools like graduated cylinders, beakers, test tubes, and scales.

Technology does not exist in isolation. Its existence relies on systems of design, manufacture, marketing, and distribution, as well as training to operate particularly complex technologies. Technological literacy, at a minimum, includes knowledge and skills

Fig. 3 A tricone bit metaphor for three dimensions of science literacy for personal and public civic action From [Tippett et al. \(2019, p. 325\)](#).

needed to work with a range of technology and to make informed decisions about the development and use of technology. Some definitions of technological literacy include communication skills, which we see as critical; consider creating or deciphering a user manual without possessing sophisticated literacy abilities! [Tang and Williams \(2019\)](#) described technological discourse as a multimodal form of language, wherein the technology community can communicate aspects of design and problem solving.

Engineering literacy

Although engineering is sometimes relegated to a complementary role with technology, we situate engineering as a separate, albeit highly interrelated, discipline with its own set of disciplinary practices. Engineering practices include identifying problems that need solving, designing solutions to problems, constructing models, applying science and mathematics concepts in problem solving, using technology in solving problems, testing and evaluating solutions, and communicating solutions. Engineering literacy can be conceptualized by articulating specific aspects of the knowledge, skills, and habits of mind that would be necessary for an engineering literate student. These specific aspects can be exemplified by the big ideas shown in [Fig. 4](#). Communication, explicitly identified as an engineering habit of mind, is also reflected in the engineering skills of engineering graphics, developing models, research and investigation, and technical writing.

Mathematics literacy (numeracy)

Mathematical literacy is the knowledge and skills needed to analyze and communicate about mathematical problems ([Organisation for Economic Cooperation and Development, 2019](#)). There are three highly interrelated components of mathematical literacy: content, competencies, and context. Fundamental mathematical content includes number sense, spatial abilities, graphing, and

Engineering Knowledge	Engineering Skills	Engineering Habits of Mind

Fig. 4 The big ideas in aspects of engineering literacy. Adapted from [Grubbs et al. \(2018, p. 35\)](#).

probability and statistics. Mathematical competencies include reasoning, modeling, and representing. Context refers to the idea that mathematical content and competencies are applied in a variety of real-world and authentic situations. Mathematical texts contain a unique set of symbols, drawings, proofs, and diagrams and students develop mathematical understanding through the interpretation of these specialized multimodal texts. Learners can also construct specific mathematical representations to communicate understanding and to build meaning. Therefore, a nuanced definition of mathematical literacy includes the ability to interpret, construct, and communicate with the vocabulary, symbols, and representations associated with the discourse of mathematics.

STEM literacy

Examination of different definitions of STEM literacy reveals two main perspectives: STEM literacy conceptualized as some combination of the individual disciplinary literacies – science literacy + technological literacy + engineering literacy + mathematics literacy – or STEM literacy as its own unique construct, wherein proponents typically take a fully integrated view of STEM. However, we are less concerned about possible distinctions between S-T-E-M and STEM literacy because our focus is on the commonalities across the disciplinary literacies. Consideration of the S-T-E-M literacies individually suggests that at a minimum STEM literacy would involve a combination of disciplinary literacies, each of which include, as outlined above, working with multimodal representations; understanding the conventions of specialized visual representations such as diagrams and drawings; and applying appropriate cognitive and metacognitive strategies (Tang and Williams, 2019).

The overarching commonality across disciplines is the ability to use the multimodal affordances of language to develop and to communicate understanding. Across all four disciplinary literacies, the language strands of reading, writing, speaking, listening, viewing, and representing have been identified as critical for constructing understanding and communicating that understanding in a variety of ways. Opportunities to work with discourse specific multimodal communications allow learners to most accurately portray their emerging understanding of concepts and can lead to cognitive engagement and disciplinary literacy. Students can strive to simultaneously make sense of the STEM concepts that they encounter while using the multimodal communication practices indicative of STEM discourse(s).

What do we mean by multimodality?

We focus on this idea of multimodality and how it might be conceptualized in order to expand our understanding of the possibilities inherent in language-rich STEM learning experiences. Modes can refer to sensory modes (e.g., sight, hearing, touch, smell, taste), or to specific ways of achieving complex communications (e.g., speech, static images, animated images, gestures, music, writing, three-dimensional models). Regardless, each mode has a range of affordances for communicating and constructing meaning; therefore, multimodal communication can harness the affordances of multiple senses, formats, and/or representations. Multiple representations, by definition, involve more than one representation, but those representations could all be in a single sensory mode (e.g., visual representations in the form of words, pictures, and symbols), or in multiple sensory modes (e.g., spoken words, printed images, and a hands-on demonstration). Multimodal approaches to STEM could include the use of multiple sensory modes (e.g., dramatic activities, a song containing STEM concepts, and reading a STEM information text) or the use of multiple presentation modes (e.g., verbal and nonverbal). In every STEM discipline, learners – as well as experts – demonstrate levels of representational fluency and conceptual understanding when they communicate using different modalities.

Thinking about multimodality in STEM

The idea of multimodal communication is well established in the individual STEM disciplines. Here we present three multimodal perspectives that have influenced our work in STEM education and in developing language-rich STEM learning experiences. Kozma and Russell's (2005) ideas about representational competence emerged from their work in chemistry, Tang's (2021) semiotic families are situated in science education, and the Lesh Translation Model (Glancy and Moore, 2013; Lesh and Doerr, 2003) was developed through studies of mathematics teaching and learning. Each of these three perspectives, although emerging from individual disciplines or subdisciplines, have broad applicability in STEM.

Our first perspective on multimodality is representational competence, which Kozma and Russell (2005) conceptualized as five levels of development in student decision making about representations. These levels are:

- *Representation as Depiction*, where iconic representations are based on physical features
- *Early Symbolic Skills*, where representations include physical features and some symbolic elements such as arrows to depict motion or time
- *Syntactic use of Formal Representations*, where representations are based on observed physical features and unobserved causes and the representational system focuses on syntax of use; representations are compared by surface features or syntactic rules rather than by underlying meaning
- *Semantic use of Formal Representations*, where representations are based on physical features and unobservable entities and processes, using a formal system of syntactic rules; representations are compared by shared meanings and can be transformed and used in problem solving

- *Reflective, Rhetorical use of Representations*, where multiple representations are based on physical features and unobservable entities and processes, using formal syntax and semantic rules; representations, or parts of representations, can be compared and transformed and used as rhetorical devices with appropriate selection and justification

Like disciplinary literacy, representational competence encompasses a range of levels, but movement through these levels is neither sequential nor permanent, instead influenced by context. While the lowest level of representational competence results in surface level depiction, the highest level emphasizes movement between and among multiple representations, harnessing the affordances of multimodality. With its focus on symbolic representations, the idea of representational competence aligns well with the language strands of viewing and representing, as well as with reading and writing.

Our second perspective on multimodality is the conceptualization of science discourse as consisting of semiotic families, with common families – modes – of meaning making including verbal-linguistic, visual-graphical, mathematical-symbolic, gestural-kinesthetic, and material-operational (Tang, 2021). The verbal-linguistic mode includes the reading, writing, speaking, and listening strands of language, regardless of language (e.g., English, French, Spanish). The visual-graphical mode incorporates representations such as diagrams and animations and includes the strands of viewing and representing and aligns with representational competence. The mathematical-symbolic mode includes mathematic and scientific notations based on numbers and symbols, which can be included in the strands of reading, writing, viewing, and representing. The gestural-kinesthetic mode consists of embodied movement and includes the strands of viewing and representing, with links to the verbal-linguistic mode. The material-operational mode captures hands-on processes such as practical work, demonstrations, and concrete model making and includes the viewing and representing strands of language as well as links to the verbal-linguistic and gestural-kinesthetic modes. Meaning making and communication involve movement between and within modes, as learners draw on the specific affordances of each semiotic family.

Our third perspective on multimodality, the Lesh Translation Model (e.g., Glancy and Moore, 2013; Lesh and Doerr, 2003), focuses on student meaning-making using common modes of mathematical models. Although there is a lack of consistency in published representations of the Lesh Translation Model, in every case, the critical aspect is the movement between and within modes such as visual representations, spoken symbols, and written symbols as shown in Fig. 5. The Lesh Translation Model clearly includes the six language strands as well as representational competence and shares similarities with the semiotic modes of science discourse. Although originating from the study of mathematical teaching and learning, the Lesh Translation Model has been adopted by researchers and educators in other disciplines, including integrated STEM.

Each of these three perspectives on multimodal communication differs according to context and focus; however, in each case, the suggestion is that deeper conceptual learning can occur when learners are able to move within and between different representations. This movement might be referred to as transformation (Kozmo and Russell, 2005) or translation (Glancy and Moore, 2013; Lesh and Doerr, 2003), but what is valued is working with multiple and varied representations as an opportunity to facilitate deeper learning. Each perspective showcases movement within and between multiple representations of multiple types. Deeper understanding of a science or STEM concept is enhanced by the ability to utilize different representational modes, to move within and between modes, and to connect modes. We argue that this translation, transformation, connection, or movement between and among representations is what makes the meaningful use of representations by students an epistemic tool in addition to a communication tool. Equally, the idea of movement is consistent with a perspective of integration in STEM teaching and learning serving as an epistemic tool. The commonality inherent in each perspective on multimodality and in integrated STEM is the emphasis on fluid

Fig. 5 The Lesh translation model. Adapted from Glancy and Moore (2013); Lesh and Doerr (2003).

movement between aspects of the construct: between multiple representational types, across semiotic families of meaning making, within and between modes, or across the STEM disciplines.

Language-rich STEM education

We have taken the position that STEM education should be integrated, because although non-integrated STEM learning experiences may still be potentially fruitful for learners, they would more appropriately be considered discipline specific. Integrated STEM learning experiences provide multiple access points for learners to think about, and construct understanding of, interrelated concepts. We have also identified language, and in particular its multimodal affordances, as a critical component of STEM education. Thus, an important goal during integrated STEM learning experiences is for students to meet curricular outcomes while learning how to use multimodal representations to create, communicate, and use knowledge within and across STEM. Advocates of integrated STEM argue that this approach is a more realistic model of what happens in the real world and can therefore more successfully prepare learners with the requisite critical thinking skills, communication abilities, entrepreneurial perspectives, and creativity to flourish in our rapidly changing society. The key benefit of an integrated approach to STEM education is the fact that the integration itself becomes an epistemic tool for students. In the act of working through multidisciplinary problems, by using and combining information and practices from STEM disciplines in an attempt to solve these problems, students are expanding their conceptual and procedural understanding of highly interrelated concepts, skills, and practices.

Instruction encouraging the effective use of multiple modes in writing-to-learn tasks is an area of study in science education. Multimodal writing-to-learn tasks have been shown to be effective instructional approaches for helping learners develop scientific understanding and these types of tasks are likely to be effective for teaching STEM. Learning benefits have been most evident when multiple modes are purposefully linked within communication tasks, regardless of context. Research suggests that students who can integrate multiple modes in science are likely to experience greater learning, in part because they are translating and transforming information across different modalities (McDermott and Hand, 2013). STEM learning environments afford numerous opportunities for translating across disciplines as well as for incorporating multiple modes to improve student understanding. A language-rich STEM learning environment allows learners to make connections between disciplines, modes, and strands of language.

A practical example of the affordances of language in STEM

A practical example of a language-rich STEM learning experience would involve multiple access points for learners to think deeply about related concepts. A STEM activity can be infused with specific multimodal tasks in order to develop an effective, integrated, language-rich learning experience. Here we describe a fairly common STEM activity – building a marble roller coaster – presented in a way that emphasizes language and its multimodal affordances. The basic materials and equipment for this activity are easily obtained: foam pipe insulation, marbles, paper cups, and masking tape. Optional materials could include markers, chart paper, graph paper, recording devices (e.g., smart phones), and tablets. As learners follow an engineering design process to plan and construct their marble roller coaster, there are multiple opportunities for educators to emphasize the roles and functions of language. For example, learners might document their plans using scaled drawings on graph paper; diagrams, lists, and sketches on paper; or mind maps in digital notepads and could document their construction processes using sketches, photographs, or videos.

During the learning experience, big ideas of science such as kinetic and potential energy, momentum, and friction emerge naturally. The technology used to design and construct the marble roller coaster can range from simple to complex, depending on the tools available and the age of the students; the end result itself can be considered a piece of technology. Aspects of mathematical literacy such as number sense, spatial abilities, and modeling and representing are central to the successful construction of a roller coaster. At any phase of the learning experience, learners utilize a variety of engineering knowledge, skills, and habits of mind, including designing under constraint, using tools and materials, creativity, and communication. Learners can communicate their growing understanding of STEM concepts by sharing a variety of representations with classmates and with their instructor. The multimodal affordances of language allow students to move between and among representations as they move between and among STEM disciplines to solve an engaging problem. In turn, the STEM learning experience provides an authentic context for developing language and literacy.

Concluding remarks

With a growing emphasis on STEM education, the role of language in STEM is emerging as a related area of interest. The multimodal nature of language is a commonality across individual science, technology, engineering, and mathematics literacies and STEM literacy. Each STEM discipline is a multimodal discourse with unique symbols and representations such as mathematical formulas, graphs, photographs, tables, animations, and diagrams, all of which are highly specialized representations and essential tools for conceptualizing STEM ideas.

STEM education can provide an authentic context in which to incorporate diverse language modes and functions. In fact, the epistemic affordances of the multimodality inherent in STEM learning environments can be leveraged to strengthen general literacy

achievement. Exploring the functions of language (e.g., interpretation and communication) and the relationship of language pairs of reading/writing, listening/speaking, and viewing/representing can provide opportunities for deeper learning.

An understanding of the affordances and limitations of different modes of communication is a crosscutting factor in science, technology, engineering, and mathematics literacies and is a key characteristic in STEM literacy. The affordances of multimodality can be more widely emphasized through purposeful STEM learning experiences such as the one described here. It is impossible to teach STEM without using language and a language-rich integrated STEM approach can help learners to simultaneously strengthen discipline specific content knowledge and literacy skills.

The purpose of this article is to broadly consider the relationship between multiliteracies and Science, Technology, Engineering, and Mathematics (STEM) education. After providing a brief introductory overview on STEM and multiliteracies, we foreground one aspect of multiliteracies (i.e., multimodality) and one aspect of STEM (i.e., engineering). We first consider the meaning of the terms *STEM* and *multiliteracies*. We then provide an illustrative example that foregrounds multimodality and engineering design. The example derives from an afterschool Engineering Literacies Club (ELC) with children ages 8–10 learning about engineering, engineering design, and disciplinary literacies (Brock et al., 2014).

Science, technology, engineering, and mathematics (STEM)

The term “STEM” originated in the 1990s at the National Science Foundation to signify science, technology, engineering, and mathematics to efficiently identify and communicate the four disciplines (Bybee, 2013). While STEM recently became a popular buzzword, the impetus of STEM education in the United States originated during the Sputnik era when science and mathematics were foregrounded in educational reform efforts. Science education documents, such as *Science for All Americans* (AAAS, 1989), *Benchmarks for Science Literacy* (AAAS, 1993), and the *National Science Education Standards* (NRC, 1996) have called for incorporation of technology and engineering into science education. More recently, the National Research Council introduced a framework for science education that highlighted the centrality of teaching science, engineering, and technology for all:

The overarching goal of our framework for K-12 science education is to ensure that by the end of 12th grade, *all* students have some appreciation of the beauty and wonder of science; possess sufficient knowledge of science and engineering to engage in public discussions on related issues; are careful consumers to scientific and technological information related to their everyday lives; are able to continue to learn about science outside school; and have the skills to enter careers of their choice, including (but not limited to) careers in science, engineering, and technology.

NRC (2012), p. 1.

This framework informed the development of the *Next Generation Science Standards* (NGSS) where engineering is situated within three distinct dimensions of science learning: disciplinary core ideas, crosscutting concepts, and science and engineering

practices. In NGSS, crosscutting concepts and relationships and convergences with literacy and math practices demonstrate the interdisciplinary nature of science and STEM. That is, crosscutting concepts such as patterns, cause and effect, energy and matter, and structure and function cut across various disciplines and unify scientific thinking about the natural world. Practices such as constructing viable arguments from evidence and critiquing reasoning from others are shared among science and engineering, math, and English Language Arts.

Despite reform documents spanning decades and the increased global interest in STEM education, there often remains little clarity and consensus as to what STEM means or what STEM education entails (Bybee, 2013). In reviewing STEM education literature, Martín-Páez and colleagues (2019) uncovered multiple interpretations of STEM education, including varying perspectives toward disciplinary integration, such as disciplinary, multidisciplinary, interdisciplinary, and transdisciplinary approaches. While they suggest that “engineering could be a discipline with a high integrating value” (Martín-Páez et al., 2019, p. 816), others have disapproved of the dominance of one discipline (Honey et al., 2014) and have instead proposed the integration of two or more disciplines (Kelley and Knowles, 2016). Certainly, from policymakers, to researchers, administrators, teachers, and the public more broadly, STEM education is conceptualized in a multitude of ways, and integration among the disciplines is still in its infancy (Dare et al., 2019).

When applied in STEM educational contexts to design, implement, and assess various initiatives, programs, and practices, this ambiguity poses genuine concerns. Given the diverse and extensive nature of work related to defining, integrating, and researching STEM disciplines, “STEM” as a domain far exceeds the parameters of what can fully be explored in this entry. For this reason, we choose to focus on only one aspect of STEM—engineering. In so doing, we recognize that engineering itself is a complex discipline which integrates science, math, and technology but is also a domain that has distinct differences and epistemic practices (Cunningham and Kelly, 2017).

In this chapter, we will focus on multiliteracies, particularly multimodality, from a pre-college engineering (i.e., K-12) education perspective. Before introducing examples of engineering, a definition and brief history of multiliteracies is likely to be helpful. To further assist readers, we also consider common terms that are often conflated with, or used interchangeably with multiliteracies.

Multiliteracies

History and principles of multiliteracies

The term “multiliteracies” originates from an article in *Harvard Education Review* by the New London Group (NLG, 1996), later reprinted in *Multiliteracies: Literacy Learning and the Design of Social Futures*, edited by Cope and Kalantzis (2000). NLG scholars have continued to elaborate and expand the framework of multiliteracies as it was conceived in 1996. Their research includes multimodality (Kress, 2010), critical discourse analysis (Fairclough, 2010; Gee, 2014), critical literacies (Luke, 2012), curriculum and learning design, (Cope and Kalantzis, 2015), multiliteracies and Indigenous perspectives (Nakata, 2001), and classroom discourse (Cazden, 2001). The NLG constituted 10 scholars who sought to expand understandings of literacy and literacy pedagogy to more equitably account for culturally and linguistically diverse societies (1996, p. 64). Although scholars’ research foci varied (see Table 1), they convened with a shared goal of reframing how educators and researchers approach literacy teaching and learning. They agreed “the fundamental problem” was “that the disparities in educational outcomes did not seem to be improving” (1996, p. 63). They collectively outlined an agenda for what they referred to as a “pedagogy of multiliteracies” (1996, p. 60; Cope and Kalantzis, 2009). This perspective was grounded equity and social justice, and confidence that new media might redefine exclusionary practices “from and by the institutions of print literacy” (García et al., 2018, p. 73).

Framing traditional literacy pedagogy as “a carefully restricted project,” the NLG posited that privileging sanctioned literacies dismissed the realities of students’ lived social worlds, and the realized realities of future occupations in a rapidly globalizing world. Developing multiliteracies was necessary because “dramatic changes in everyday life in the realms of work, citizenship, and identity” rendered traditional literacy pedagogy practices “anachronistic” (Cope and Kalantzis, 2015, p. 3). The NLG proposed that

Table 1 New London Group scholars described in Cope and Kalantzis (2000).

Scholar	Location	Research focus
Courtney Cazden	United States	Classroom discourse, literacy pedagogy
Bill Cope	Australia	Cultural diversity in education literacy pedagogy
Norman Fairclough	Great Britain	Language changes represent of sociocultural changes
James Gee	United States	Discourse and psycholinguistics in capitalist jobs
Mary Kalantzis	Australia	Social education, literacy, citizenship education
Gunther Kress	Great Britain	Language, semiotics, visual and multimodal literacies
Allen Luke	Australia	Sociological analysis of teaching reading and writing
Carmen Luke	Australia	Feminist pedagogy
Sarah Michaels	United States	Learning in diverse urban classrooms
Martin Nakata	Australia	Literacy in indigenous communities

developing a multiliteracies approach was imperative in a diverse and globalized world, especially to address the gap in educational access and equity among diverse students and to “ensure that differences of culture, language, and gender are not barriers to educational success” (NLG, 1996, p. 61). Responding to this challenge, NLG prioritized “creating the learning conditions for full social participation,” where “the issue of differences becomes critically important” (1996, p. 61). NLG’s primary concerns included “pedagogical tension” between teaching methods, response to increasing diversity, the development of new modes and technologies, and “changing text usage in restructured workplaces” (1996, p. 62).

In 2022, these are even greater challenges. In the United States, for example, classrooms are increasingly linguistically, racially, and ethnically diverse, and repeatedly concerns are raised about test scores. For example, students in high-poverty schools are more likely to have lower math and reading scores across all racial and ethnic groups (National Center for Education Statistics, 2019). Persistently, such standardized measures have presented deficit-oriented portraits of students of color and multilingual learners as these assessments are not valid indicators of students’ intellect, holistic knowledge, or potential and have thus contributed to furthering racial inequality in education (Au, 2016; Hagopian, 2014; Menken, 2008; Milner, 2012; NASEM, 2018). Less scholarship has considered how inequitable opportunity structures and opportunities for learning contribute to the systemic inequities undergirding student performance. From its genesis, the multiliteracies framework sought to address inequities and consider how to transform pedagogy and schools to create opportunities for all learners (Cope et al., 2018). This focus on equity is foundational to multiliteracies perspectives.

Multiliteracies and metalanguage to describe and interpret design elements and modes

Prompted by global shifts in communication, the NLG (1996) considered literacy and learning in relation to multiple dimensions pertaining to multiliteracies, multimodality, and multilingualism. The term *literacies* plural provides reference not only to skills-based decoding of words or print, but also social meanings, ideologies, and emerging forms of literacy practices. From the outset, multiliteracies were linked with active design and transformation of teaching, curriculum, and educational contexts. Multiliteracies included multiple modes for meaning-making while recognizing the continued need for overt instruction. Underlying concerns about shifts in communication, labor, and society were considerations of equity in schooling and how futures are shaped by schooling. Ideas pertaining to design and pedagogy also included *situated practice*, *overt instruction*, *critical framing*, and *transformed practice* (NLG, 1996, p. 88). Some design elements were expressed in a well-known figure: “Multiliteracies: Metalanguages to Describe and Interpret Different Design Elements of Different Modes of Meaning” (see Fig. 1). Scholars have continued to define particular aspects of the figure such as mode and multimodality (e.g., Kress, 2009, 2010; Kress et al., 2001). Likewise, others have continued to refine additional key ideas such as situated practice, overt instruction, critical framing, and transformed practice as these pertain to multiliteracies (see Cope and Kalantzis, 2009, 2015; Kalantzis et al., 2005). Scholars continue to explore multiliteracies as evolving and contemporary (Serafini and Gee, 2017) and in contexts of diversity (Boyd and Brock, 2015), critical media literacy (Mirra et al., 2018), technologies (Lewis Ellison & Kirkland, 2014), transnationalism (Skerrett, 2015), and other topics.

The original NLG “call to understand knowledge and pedagogy as multimodal was radical” (Jewitt, 2009, p. 19) although in the past decade, many disciplines have turned toward multimodality. In traditional schooling, teaching and learning and academic curricula have centered primarily, and often exclusively, on linguistic design of meaning-making (i.e., reading words, writing words, speaking words). In contrast, the NLG proposed that audio, spatial, gestural, and visual design should also be considered in both teaching and learning. While not fully elaborated, multimodality was recognized as the embodied processes of literacy learning and teaching (McVee et al., 2017a). As such, literacy was not viewed as limited to skills of reading words or writing words but was situated in cultural contexts and enacted through embodied practices. The NLG is a keystone in many explorations of multimodality because of the ways that the original NLG manifesto (1996) pressed literacy scholars to consider and investigate multiliteracies and multimodality.

Clarification of terms often used interchangeably or conflated with multiliteracies

In the literature, the term “multiliteracies” is often used interchangeably or conflated with other terms. Upon encountering these varied terms, those new to multiliteracies might wonder: What are the distinctions between *multiliteracies*, *multimodality*, *new literacies*, *New Literacies*, and *New Literacy Studies*? Do these differences matter? In this section, we take a small step toward answering these questions. The explanations here are, by necessity, brief and partial. The goal is to provide readers with a rudimentary definition of terms while including sign posts for further reading and exploration, since the complexity of these particular terms and their history cannot be thoroughly presented here. We begin with a discussion of New Literacy Studies (NLS), a movement that emerged prior to the drafting of the NLG multiliteracies publication and whose scholars had a profound impact on the development and legacy of multiliteracies.

New Literacy Studies (NLS)

Grounded in the ethnography of communication, NLS is a foundational framework that has foregrounded ethnographic explorations of local contexts whereas multiliteracies has primarily foregrounded pedagogical considerations grounded in global and historical contexts (Cope and Kalantzis, 2009). There is, however, significant overlap between NLS and multiliteracies. Street (2012) noted that NLS is an approach that “entails the recognition of ‘multiple literacies’” (p. 27). NLS is founded upon

Fig. 1 Multiliteracies: metalanguages to describe and interpret different design elements of different modes of meaning (NLG, 1996, p. 83). Reprinted with permission from The New London Group, A pedagogy of multiliteracies: designing social futures, Harvard Educational Review, Volume 66:1 (Spring 1996), pp. 60–92. Copyright (c) by the President and Fellows of Harvard College.

scholarship from varied disciplines and the ethnographic or contextualized study of discourse (Gee, 2015). In particular, as postulated by NLS scholars (e.g., Barton, 1994; Gee, 1990; Heath, 1983; Street, 2003), multiliteracies and NLS share an emphasis on literacy as socially and culturally situated. A key distinction for many NLS scholars is that of literacy events and literacy practices. Grounded in a landmark ethnographic study, Heath (1982) identified a *literacy event* as “any occasion in which a piece of writing is integral to the nature of the participants’ interactions and their interpretative processes” (p. 93). Based in part on his ethnographic work in Iran, Street (1984) argued that literacy was more than mere acquisition of technical proficiency or skills in reading or writing—what he referred to as the “autonomous model of literacy” (p. 19). Street (1984) posited that “literacy practices” (p. 1) were embedded in social practices that depend “upon the context and the nature of the social formation” (Street, 1984, p. 1). Street (1988) further observed that literacy practices are broader than literacy events because they incorporate literacy events and the “ideological preconceptions that underpin them” (p. 61). Other scholars have continued to explore these distinctions (e.g., Barton et al., 2000; Burnett and Merchant, 2020) and have also considered NLS and multimodality (e.g., Rowsell et al., 2019).

Multimodality

In their original publication, the NLG (1996) posited that “One of the key ideas informing the notion of multiliteracies is the increasing complexity and inter-relationship of different modes of meaning” (p. 78). They indicated modes pertaining to linguistic, visual, audio, gestural, spatial, and multimodal design (see Fig. 1). The NLG differentiated multimodal design from other modes noting: “Multimodal Design is of a different order to the other five modes of meaning; it represents the patterns of interconnection among the other modes” (NLG, 1996, p. 78). Multiliteracies are thus inclusive of, but not the same as, multimodality. Researchers who explore multimodality often draw upon social semiotic theories of literacy (e.g., Lemke, 1989, 1998; Kress, 2010; Kress et al., 2001) and may frequently draw from or combine these with systemic functional linguistics (e.g., Jewitt et al., 2016; Unsworth, 2008). Regardless of the theoretical frameworks used, multimodality considers the ways in which people draw upon all modes to make meanings (e.g., combining images with print, using a gesture, using a gesture with a word and an image and so on). Body position, colors, movement, and sound are also explored in multimodal studies (Jewitt et al., 2016). Multimodality is frequently linked to multiliteracies (Mills, 2009), new literacies (Albers and Harste, 2007), and New Literacy Studies (NLS) (Rowse et al., 2019).

new literacies

The lowercase phrase, “new literacies,” typically encompasses the varied, emerging, and rapidly changing ways that literacy is being transformed beyond reading and writing of alphabetic text. Street (2003) has focused “what it means to think of literacy as a social practice,” (p. 77) distinguishing between literacy as a technical, and neutral skill, and literacy as an ideologically and culturally situated practice. Some authors foreground the affordances of multimodality in making literacies new, whether through traditional means such as art (Albers and Harste, 2007) or digital means for multimodal composing (Miller and McVee, 2012). Scholars also explore the ways in which digital texts and online contexts shift the reading strategies and positions of readers (Leu et al., 2008) with emphasis on social aspects of literacy (Lankshear and Knobel, 2011). The impact of new literacies on learning and design—what Cope and Kalantzis refer to as “learning by design” (2015)—is another thread of new literacies. Writings related to new literacies wend their way through landscapes of political, social, cultural, and technological change and share a common goal of transforming education and learning for teachers and students.

New Literacies

New Literacies foregrounds the Internet and the ways in which digital literacy, particularly the Internet and all it affords, is transforming literacy. As the editors of *The Handbook of Research in New Literacies* put it, “How do the Internet and other information and communication technologies (ICTs) alter the nature of literacy?” (Coiro et al., 2008). Leu et al. (2019) distinguish between a theory of New Literacies with uppercase N and L and new literacies, all in lowercase letters in what they refer to as a “dual level theory” (p. 324). Specific types of literacy changes or new forms of social communication such as text messages are “new literacies” (see pp. 325–326). As a broader theory, *New Literacies* conveys a sense of what happens across various domains where new literacies are emerging, and common patterns that emerge are “included in a broader, common, New Literacies theory” (p. 326). Gee (2015) refers to the New Literacies, as a “natural offshoot” (p. 44) of New Literacy Studies (NLS). It should be noted that while Leu and colleagues, Gee, and others have at times made careful distinctions between new literacies, New Literacies, and New Literacies Studies, not all authors adhere to these distinctions, particularly in earlier writings.

Having briefly introduced multiliteracies and terminology, the next section provides an illustration of one aspect of multiliteracy (i.e., multimodality) one aspect of STEM (i.e., engineering). Through this illustration, we explore multimodality and engineering literacies while foregrounding considerations of equity.

Multimodal literacies and engineering design

In a recent state-of-the-art literature review studying engineering, disciplinary literacies, and communication at the pre-college (K-12) level, a strand of research which focuses on studies using the perspectives of multimodality and multiliteracies has emerged to explain interactions within student engineering design teams (Silvestri et al., 2021). These studies purposefully foreground the ways in which engineers communicate their ideas, designs, arguments, and other meanings using a plethora of tools as well as multiple modalities for communication beyond speech and writing (e.g., demonstrations, gestures, inscriptions, etc.). Some publications foreground the multimodal nature of communication within design teams (Jordan, 2010; McVee et al., 2017b; Shanahan et al., 2016) whereas others foreground the types of multimodal tools (including digital notebooking) used to convey design ideas (Shanahan et al., 2017) or disciplinary literacy with multilingual learners (Paugh et al., 2018).

Within this strand of engineering and literacies research, special attention has focused on how foregrounding multimodal communication practices within engineering design teams can be of particular benefit for multilingual learners (McVee et al., 2017b; Shanahan et al., 2016; Shanahan et al., 2022). This intersection of engineering education and literacy research revealed “researchers attending to the power of multiple modes of communication, of ways students can be encouraged to interact with each other beyond linguistic means, and of the beneficial consequences of such practices for inclusion of English learners in STEM activities” (Silvestri et al., 2021, p. 10). It should be noted that multimodality is not limited only to engineering as increasing numbers of scholars have considered the role of multimodality in other STEM areas, for example, in science

(e.g., Grapin, 2019; Lee et al., 2019; Lemke, 1998; Tucker-Raymond et al., 2007; Varelas and Pappas, 2013; Wilmes and Siry, 2020; Williams and Tang, 2020).

Engineering and engineering design literacies are explored in the following example. After a brief description of participants and context, we explore the “communicative literacies” (Silvestri et al., 2021, p. 2) of students engaged in an engineering design task. Students engage in a broad range of multiliteracies practices. Primary analysis focuses on multimodality through analysis of gesturing, sketching (i.e., images), touching and handling materials, and speaking. The episodes illustrate how young, novice designers engage in *problem-scoping*, a process essential in engineering design. Watkins et al. (2014) define problem-scoping as: “the process of discovering and understanding aspects of the problem that need consideration” (p. 44). We explore the questions: What types of multimodal communication are used by children during the engineering design process? What do these multimodal communications reveal about problem-scoping?

Context and participants

The examples in this article derive from an elementary ELC in the northeastern United States. The ELC met after school twice a week for 1 h per session over seven weeks. The ELC was developed by elementary school teachers, university literacy faculty, and university engineering faculty and designed to serve children in grades three through five (i.e., 7–11 years of age). The purpose was to introduce engineering, teach basic engineering design principles, and stimulate interest in engineering, especially for groups who are minoritized in engineering as a college major and profession (e.g., students of color, girls). In particular, school leaders, teachers, and researchers agreed that students who were classified as English as a New Language (ENL) students (i.e., the state’s term for multilingual learners) should be specifically encouraged to participate. Additionally, students were accepted in the ELC regardless of academic standing.

The ELC used project-based learning (Krajcik and Shin, 2014) and engineering design process models (e.g., NASA & Design Squad PBS Kids, 2021) as a basis for minilessons, interactive discussions, and design challenges in small groups that would support the foundations of engineering knowledge and practices. While most sessions began with minilessons and interactive discussions, most of ELC was spent with students in design pairs or teams of up to five students, providing children the opportunity to design and build a bridge model, construct a rubber-band powered car, and create an amplifier that could be used with mobile devices to play music.

Data was collected throughout the ELC using audio recording, video recording, and fieldnotes. Student artifacts (e.g., drawn designs, photos of built designs, writing) were also collected. Audio and video recordings were transcribed; analytic memos written during transcription were used in analysis. Episodes in this article focus on fourth-grade girls, Ameena and Emma, as they designed a model bridge. Ameena, age 10, is an Arabic-English speaker. Emma, age 9, is a Chinese (Mandarin)-English speaker.

An exploration of multiliteracies in engineering literacies club (ELC)

The third- and fourth-grade students in ELC huddle together at the carpet watching a historical video clip (British Pathé, 2013) of the Tacoma Narrows Bridge collapse (<https://www.youtube.com/watch?v=XggxeuFDaDU>). After the dramatic finish, the lead teacher, Mrs. Stasik, prompts:

What do you notice? What do you wonder? You are going to go and design and build a bridge today with your group. What can you learn from this to help you with your design?

Within the whole-group setting, most children turn and talk to one another animatedly. Mrs. Stasik asks, “Did anyone’s conversation have to do with shapes? I’m not saying you are right or wrong; I’m just curious.” Ameena says, “I think there was something about designing with triangles.”

This discussion is situated in knowledge built across three previous sessions where students had been introduced to engineering, learning through failure, and engineering design process models (NASA & Design Squad PBS Kids, 2021). Children were introduced to engineers as people who solve problems and engage in productive communication (Shanahan et al., 2016). Children explored how technology could solve problems, pondering whether bridges were technology. Children wrote and discussed responses to questions such as: *What do bridges do for humans? What problems do bridges help with? Who builds bridges? What are bridges made of? What are some different kinds of bridges?* Ameena’s mention of triangles is a specific reference to a prior ELC session on strong shapes from TeachEngineering.org (2021). Although designed for older learners, ELC planners adapted the lesson for younger learners, for example, adding an activity using magnetized plastic rods to enable students to experiment with how shapes help create sturdy structures.

On this day, Ameena’s comment about triangles launches a conversation about how triangles can provide support for weight-bearing structures and provides an authentic and interactive review led by Mrs. Stasik. Mrs. Stasik then introduces and discusses the Client Requirements on a PowerPoint slide (Fig. 2). She reminds the children that individual sketches from the previous session were a type of brainstorming. She encourages them to communicate and plan before they build, stating “Communicating can look like sketching, talking, sketching, a mix of that, but before you get materials you need to have a plan. Mrs. Stasik uses the

Fig. 2 Engineering literacies club bridge project client requirements.

PPT to introduce the Design Review Checklist for planning. Building on the previous sessions, she reviews images of bridges (e.g., truss, suspension, beam, arch) stopping for discussion of ideas on how triangles are strong shapes. She reviews the engineering problem (i.e., designing a bridge that will reduce traffic backups and pollution, span the river, see template Fig. 4, and allow boats to go under it). A student asks if they will get a copy of the design requirements. With typical enthusiasm, Mrs. Stasik responds: “Yes, it’s in your baskets! What a good question. You are thinking like an engineer!” She adds that the Engineering Problem, Client Requirements and copy of the engineering design process are on the tables which are covered with paper for sketching. She reminds students of the requirement to use a variety of materials and projects a slide that shows images and labels of all materials, adding that this is also on the table. A student responds, “If we didn’t have that paper, then we would’ve forgot what ... materials there were.” After a few additional reminders, students move into their design teams.

Phase 1: Aameena and Emma begin to sketch bridge designs

Aameena and Emma settle down to work on their bridge design. Aameena holds her sketches made the previous session out toward Katie (second author on this article). She asks Katie, “Can I redraw? I want to make changes.” Katie affirms that they can certainly change their designs. Aameena then turns to Emma and says, “Let’s draw together, so we both agree with it.” Aameena starts sketching. Emma watches her and then begins drawing. When they have sketched for a while, Aameena looks away from her own sketch, which she has just erased. Aameena asks Emma “What kind of bridge?” In response, Emma says, “We should make the top ...” and gestures over the bridge in an arch (Fig. 3). Her full meaning is made apparent only in the gesture over the arch. Meanwhile, Aameena leans in, gesturing over Emma’s sketch and asks several questions. Then, Aameena begins a new sketch. As they sketch, the girls make comments about their designs.

This interaction between Aameena and Emma demonstrates multimodality as essential in communication and learning. The girls use spoken words (i.e., a linguistic mode) to communicate, but meanings do not reside in the words alone. Meanings are situated within the context and represented in artifacts such as the paper drawing (i.e., design images from the previous day) and the emerging sketch (i.e., the emerging image they are co-creating on this day). Additional affordances for meaning are present in Emma’s gesture—the movement of her hand across the span of the bridge arch represented on paper which, as noted, is not merely complementary to her speech but essential because words alone do not convey the full meaning. Her gesture brings a unique

Fig. 3 Emma using an arch-like gesture to communicate with Aameena. Note. This shows the beginning of Emma’s sketch. She later augmented the arch with more lines (i.e., triangles), showing the trusses.

contribution to the conversation (Goldin-Meadow and Alibali, 2013), referring to the visual-spatial form of the arch. The gesture, known as an “iconic gesture” (Roth, 2001, p. 370) is similar to the arch itself. Emma combines gesture with speech and the sketch (i.e., a representation) to complete her meaning.

When considering the practices of real-world engineers, sketching is an important mode of representation, and representations are essential in engineering design (Johri et al., 2013). Ferguson (1992, cited in Brun et al., 2016, p. 3) describes three types of sketching: “‘thinking sketches’ made by an engineering looking for new ideas, ‘talking sketches’ made when two engineers communicate, and ‘prescriptive sketches’ that are meant to please and convince people outside the design process” (Brun et al., 2016, p. 3). As the girls begin their collaboration, Ameena positions the sketch specifically as a means to communicate; she says “Let’s draw together, so we both agree with it.” Ameena and Emma do in fact use the drawing this way, exchanging different ideas while gesturing to and adding onto the drawing. The drawing mediates their design planning. In contrast, Ameena’s previous design can be viewed as a thinking sketch made for herself. On this day, the girls develop seven different sketches. (Sketches 4–7 will be introduced in the following section). The sketches function to help them communicate and clarify their ideas and reveal valuable insights into how budding engineers may engage in approaching collaborative problem-solving and design. Their approach to the sketches can also be seen as an example of “establishing collaborative group work,” a type of problem-scoping (English and King, 2017, p. 348).

Phase 2: Emma and Ameena shift their planning to include the template

At this point, Mrs. Stasik gives the group a river template (i.e., cardboard with blue lines and ripples) that will help students conceptualize the required length of the bridge to span the river (Fig. 4). Ameena promptly asks if they are able to draw on it, and Mrs. Stasik says yes but to use a pencil. The river template jumpstarts a new cycle of brainstorming and designing efforts mediated by rich intersections and affordances of the modalities of gesture, drawing, and speech. The physical artifact (i.e., river template) provided by Mrs. Stasik prompts a conversation about their design planning (i.e., problem-scoping (Watkins et al., 2014)).

Ameena:	So, um, let’s think of how we’re gonna do it before we draw.
Emma:	Yeah.
Ameena:	So, this this is it, and this is the river. So, if this is, like, water then land over here,
Emma:	Yeah.
Ameena:	The bridge would start right here.
Emma:	Right.
Ameena:	Oh the bridge would start here and then would like ... there’s room for people to walk on ... like that ...
Emma:	Yeah.

Ameena’s comment that they should “think” before they draw, and Emma’s agreement, indicates that they do not merely jump to solutions for the problem (i.e., bridge-building) without forethought but seek to further understand the problem. The girls focus their gaze on the template, noting which parts represent the land and which parts represent the water. Similar to students studied in Watkins et al. (2014), a nuanced, contextualized exploration of the girls’ interactions reveals an on-going process of problem-scoping (i.e., exploring and describing the boundaries of the problem they are to address). This consideration is key because most studies of expert and novice designers, often in an undergraduate engineering context, indicate that novices treat design tasks

Fig. 4 The river template provided by Mrs. Stasik prompts a conversation about design plans.

as “a well-defined straightforward problem they prematurely attempt to solve” (Crismond and Adams, 2012, p. 748). In contrast, others (e.g., Ehsan and Cardella, 2020; Watkins et al., 2014) argue that nuanced, contextualized portraits reveal complex processes of problem-scoping even with children.

The girls continue to consider how to address their bridge design, specifically, engaging in what Ehsan and Cardella (2020) refer to as “problem-framing,” which is “adding/considering meaningful context” (p. 15). This meaningful context includes the physical artifact (i.e., the cardboard template) and the representative elements of the template (i.e., how the template represents land and water). The template serves as a mediational artifact (Roth et al., 1999; Pahl and Rowsell, 2010) that helps to support and refine their design process and requires them to grapple with issues of scale, engineering criteria, and constraints.

The girls begin to consider how their bridge design, which included beams and an arch with triangular trusses, might be represented on the template. As they talk, Ameena begins a smaller fourth sketch just below the template on the paper covering the table. She says “we should make the triangles under” but does not finish her thought. Emma asks, “Under what? Like, on the side? I mean, like, make our arch and so we can put it [triangles] like, through it?” Emma is quietly explaining her idea, gesturing to the paper. Ameena looks perplexed. “Can you draw it?” she asks. Emma makes a few gestures in the air and then begins a fifth sketch on the paper in front of her, pausing occasionally to gesture. She continues to explain what she is doing (i.e., adding the triangles through the arch). “Oh! Yeah, yeah, I get what you’re saying. So it’s like ...” Here Ameena rapidly draws an arc and draws triangles underneath it—the sixth sketch. Then she crosses out the drawing. She turns back to Emma pointing a pencil at Emma’s sketch asking: “Is there, like, gonna be some [something], like, here, too, for the cars?” Emma corrects her “No, like this” indicating where cars will traverse the bridge. “I get it,” Ameena says. “Let’s start drawing.”

Using pencil Ameena lightly draws the trusses (i.e., arches and triangle supports discussed in previous sessions) and columns supporting the platform—their seventh sketch—onto the template, constantly looking back and forth to the drawing that Emma had drawn on the table and talking with Emma. While drawing sidewalks on the side of the bridge as Emma suggested earlier, Ameena comments “And then here is where the, um,” and where she pauses, Emma interjects “the people part” goes. In this process, the girls work to combine their first drawings with clarifications they had recently sketched, so they can represent how their design will fit onto the cardboard template. They communicate through visual and gestural modes with little speech. Even when explaining verbally, few words are used. Ameena’s and Emma’s communication is indicative of what Schon (1992) observes about individuals engaged in design processes: “Designers know more than they can say, tend to give inaccurate descriptions of what they know, and can best (or only) gain access to their knowing-in-action by putting themselves into the mode of doing” (p. 131). Their use of the cardboard template represents how design is both social and material (Roth, 2014, 2017; Schon and Wiggins, 1992).

Across the phases of the project on this day, Emma and Ameena develop seven sketches. The first three sketches are individual designs developed while exchanging comments, questions (i.e., talking sketches). Ameena abandons her fourth sketch; not understanding what Emma is telling her, she asks Emma to draw a fifth sketch which Emma does. Ameena listens to and watches Emma sketch, but quickly turns and produces a sixth sketch copying Emma’s which she quickly scribbles out (i.e., clarifying her own understanding). Ultimately, Ameena draws the seventh and final sketch but does while referring back to Emma’s fifth sketch.

The final seventh sketch (see Fig. 5) is a very light pencil drawn on the cardboard. Throughout the episode, the girls communicate nonverbally through the sketch (i.e., image) but also through gestures (e.g., pointing to or making gestures over the images to demonstrate shapes or relevant aspects of the design). Their nonverbal communication is layered with verbal interactions. While their communication and disciplinary knowledge lacks the sophistication of practiced engineers, their use of drawing mirrors adult designers who use sketching for multiple purposes (Brun et al., 2016). Their sketching also represents characteristics described by de Vere et al. (2011) who note that “Sketching is a fluent and flexible process, producing implicit, abstract and inexact representations of possibilities, rather than well-defined solutions” (Section 4.1, n.p.).

Fig. 5 Ameena gestures across the triangles sketched on the template.

Phase 3: Emma and Ameena discuss and plan which materials to use

After completing their drawing on the cardboard template, Ameena prompts yet another round of pre-planning. She says:

So, before we start making this [the bridge], let's see what| how we're gonna make it first. So, do you think we should use the clay to make this part? (She gestures indicating the platform of the bridge). And then ... and then we use| bamboo sticks to make this. (She gestures across the triangle shapes drawn on the template. [See Fig. 5]).

Emma suggests instead that they use popsicle sticks and that they could go under the bridge to support it. When Ameena suggests using glue, Emma says to glue it and then put the clay on the popsicle sticks under the platform. They decide to use wire to make their arch.

Here, the girls engage in a number of problem-scoping activities that Ehsan and Cardella (2020) label “information gathering” (p. 15) by “exploring material” (p. 15). The girls first do this conceptually and verbally, referencing the drawn design and available materials. They discuss their materials with reference to their drawing on the template, frequently gesturing to the template (Fig. 5). As the girls complete their design and materials discussion, researcher Katie, who is taking notes nearby, asks them to explain their drawing. The girls explain how their built design will take shape and the materials they will use. Mrs. Stasik then checks in, and after a quick update, Ameena and Emma go to the materials table.

Phase 4 : Ameena and Emma gather materials and organize guides

After returning from the materials table, the girls engage in organizational planning practices. First, they prop up the cardboard template so they can refer to the image drawn lightly in pencil. On the table directly in front of them, they carefully arrange left to right: *Client Requirements* (see Fig. 2), *Checklist, Your Engineering Problem*. Only after setting out all the guide sheets do they begin working with the modeling clay that will serve a base for each pillar (see Fig. 6).

These organizational practices are similar to the ways practicing engineers might review client requirements and the problem they are tasked to solve. The girls situate printed client requirements, checklist, and engineering problem centrally. They do not explicitly review the guide sheets verbally, but place them where they can use them authentically as visual and mnemonic devices. Here, the girls are engaging the use of print text as a disciplinary literacy (i.e., using text in a specific disciplinary manner). They then begin working with the materials (e.g., modeling clay) and continue building in a collaborative manner.

Discussion

Problem-scoping is often included as one step in engineering design process models. Similar to others who have studied problem-scoping (e.g., Ehsan and Cardella, 2020; Watkins et al., 2014), in Emma and Ameena's group, problem-scoping was not limited to one step. Examples of problem-scoping exist on earlier days or whole-group settings as the problem was being introduced to the children. Later, after building their bridge, the girls also engaged in problem-scoping when they arrived at ELC and found their structure had collapsed. Problem-scoping was essential in fixing the problem and redesigning their structure. Comparable to Ehsan and Cardella (2020) and Watkins et al. (2014), the examples from Emma and Ameena show that the problem-scoping of young learners is more nuanced and sophisticated than has been portrayed by some (e.g., Crismond and Adams, 2012). When considered from a multimodal and multiliteracies perspective, the episodes presented here constitute several considerations and possible extensions for scholars of communicative literacies and engineering education, particularly when considering engineering design.

First, we explicitly attended to multiple modalities (e.g., gaze, gesture, touch, object and materials handling) in addition to spoken interactions, noting the ways in which meaning resides in these embodied processes and beyond the words spoken. We explored multiliteracies of engineering through “communicative literacies” (Silvestri et al., 2021, p. 2). In their review of the

Fig. 6 Template and guide sheets with materials chosen for bridge construction.

communicative literacies of engineering design, Silvestri et al. advocated for additional research on communicative or disciplinary literacies and posited that the multiliteracies framework could be applied to interdisciplinary studies of communication in K-12 engineering design teams. Specifically, Silvestri et al. proposed use of social semiotics (e.g., Kress, 2010; Norris, 2004) which can “provide a nuanced theoretical framing and vocabulary through which to consider within-group interactions” (Silvestri et al., 2021, p. 17). While numerous explorations of science have considered the registers and repertoires of language in science using social semiotics (e.g., Lemke, 1989, 1990, 1998; Halliday and Martin, 1993), there are, as yet, limited investigations of engineering design processes, especially for younger learners, using a multimodal lens. As part of the framework of multiliteracies, multimodality underscores the varied and rich resources for making meaning. In the episodes presented here, the process of sketching representations (i.e., images) are a nexus through which Emma and Ameena engage with ideas and problem-scoping. In these instances, the sketches take on the superordinate position followed by other modes such as gesture and speech.

Second, we explored how images, represented through sketches and the sketching process, play a role in the girls’ problem-scoping. Goldschmidt (2003) posits that “sketching assists in generating ideas and strengthening them by interpreting the ‘backtalk’ of a sketch in progress” (p. 72). She describes how children “read” drawings and that “designers habitually practice a similar process in the early idea-generation phase of the design process” (p. 72). Interestingly, while many engineering educators begin by emphasizing what experts do (Crismond and Adams, 2012), Goldschmidt uses the process of child development as a starting point and then argues that what expert designers do when sketching is actually an extension of what most children learn to do as they develop.

Few studies examine young children’s drawings during the engineering design process, but those that do typically explore the connection between children’s sketches and the outcome (i.e., built object) (Portsmore et al., 2012). Some researchers have found little or no correlation between sketching and outcomes (Rogers and Wallace, 2000), while others identified varying relationships (Fleer, 2000; Portsmore, 2009). Although Emma and Ameena ran out of time to build their arch, the built artifact (i.e., bridge) bears a strong resemblance to their sketches with pillars, trusses, and platform. Goldschmidt (2003) posits that the connection between the drawing and the built artifact is not the most crucial point. Goldschmidt proposes that sketching is important because: (1) sketching promotes idea generation; (2) sketching can be individually or collaboratively generative, and (3) sketching provides opportunities for reflection (Schon, 1983). The processes of drawing and multiple iterations as represented in Emma’s and Ameena’s designs and their multimodal engagement supports multiple types of problem-scoping. One paramount outcome is the disciplinary communication and meaning-making that takes place through, around, because of, and in response to the sketches and the utilization of other modalities.

The sketch affords opportunities for partners to seek clarification, work toward collaborative consensus, correct a partner’s misunderstandings or questions, and consider materials. These outcomes/processes/affordances of sketching are pertinent because they reveal the power of multiliteracies: Multiple semiotic signs (i.e., gestures, drawings, words) work together (i.e., inter-semiotically) to position learners. This meaning is not expressed in any one outcome—whether that outcome is a sentence or a built artifact. Meaning resides in the situated context and semiotic modes unfolding across time. Multimodality thus has tremendous power and potential to position young learners with multiple opportunities to learn. While Ameena and Emma’s final artifact (i.e., bridge) did, in fact, resemble their sketches, the resemblance is less significant than the processes of disciplinary communication and problem-scoping that they engaged in. From this vantage point, their position is not that of the deficit, a position often ascribed to students who are not yet fully bilingual. Rather, Emma and Ameena are positioned within the ELC community as competent problem-solvers and designers who can communicate using *multiple* semiotic signs. These signs may not yet include spoken words that indicate “precision as exactness in communicating disciplinary meaning” (Grapin et al., 2019, p.71), but this does not limit their opportunities for problem-solving or learning. Furthermore, as Roth (2017) observes “when students have the opportunity to design and produce engineering artifacts, their communicative competencies initially tend to be tied to work-related movements and materials for doing and exhibiting what is required to get the job done” (p. 257). Bodily movements thus ground abstract discourses with which students later engage (Roth, 2015).

Conclusion

Reflecting on multimodality and multiliteracies perspectives in engineering and STEM, several factors come to the fore. First, teachers are crucial in designing environments where multiliteracies can flourish. While the teachers do not figure prominently in the episodes described in this article, the teachers were responsible for creating a community where the multiple modes and language about design (Fig. 1) were used for learning and teaching. The teachers provided “overt instruction” (NLG, 1996, p. 88) or what Kalantzis et al. (2005) later identified as “conceptualizing” (p. 74) as needed to assist young learners. With regard to engineering and engineering design, teachers supported “defining and applying concepts” and “putting the concepts together that make discipline knowledge” (Kalantzis et al., 2005, p. 74). The ELC was created to engage in “situated practice” (NLG, p. 88) related to engineering and engineering design. Kalantzis et al. (2005) later labeled this “experiencing,” drawing upon “personal knowledge, evidence from learners’ everyday lives,” and “immersion in new information and experiences” (p. 73). This notion of engineering is particularly integral because engineering is a situated and material-centric practice (Johri et al., 2011).

Second, the context, where all learners engaged with engineering activities and the engineering design process regardless of their language background, academic standing, gender, or other characteristics, was essential to the success of the ELC. Following the NLG’s principle of equity for all students, the teachers, school leaders, and researchers agreed that no child would be excluded from ELC, particularly students who are minoritized in engineering careers. Multilingual students were encouraged to participate

regardless of their classifications in state hierarchies of language proficiency, and no students were excluded due to academic standing. The educators who established the ELC assumed that if multimodality was leveraged as a resource in a materials-rich engineering environment, students, especially multilingual learners, would thrive. In this way, the founders of the ELC took a step toward a more critical engineering design process pedagogy.

As always, there is room for improvement in teaching and learning for raising critical consciousness. In looking back on these episodes and others in the ELC, there could have been opportunities to directly link to students' and families' "funds of knowledge" (Gonzalez et al., 2005) to solve engineering problems in the school or engage in community-centered engineering projects (Jordan et al., 2021). While students learned about engineers as problem-solvers and some problems did address local community inequities, ELC could have included more direct exploration of critical literacies, justice, and equity pertaining to the "health, safety, welfare of the public" (Wilson-Lopez et al., 2017, p. 242) to help children foster deeper connections and critical perspectives of engineering (McGowan and Bell, 2020). While students were positioned in a non-deficit manner, more could have been done to explicitly create linkages that were asset-based approaches to engineering (Martin and Wendell, 2021) to further enhance opportunities to learn. Young engineers could also be introduced to multimodality as a resource for "futuremaking" (Turner and Girffin, 2020, p. 109) to envision themselves in STEM-related careers.

Researchers of engineering education can also learn much from the NLG (1996) multiliteracies framework and the outgrowth of multimodal research since the first publication of the multiliteracies framework. Writing in the *Journal of Engineering Education*, Case and Light (2011) noted that more diverse methods are needed in the study of engineering education and more explicit discussion of methods is needed. Multimodal methods (e.g., Norris, 2004; O'Hallorin, 2013) and multiliteracies bring methodological pluralism needed in studies of engineering education. Multimodality and multiliteracies can readily ground asset-based research approaches to engineering education, thus contributing to both classroom practice and research. In particular, multimodal research methods can surface non-linguistic communication that occurs frequently during the engineering design process, thus avoiding over-emphasis on verbocentric processes and outcomes that too often characterize research, teaching, and learning.

The 21st century is an era of knowledge and economic globalization, and more and more attention is paid to scientific and technological innovation. With the increasing demand for science, technology and engineering talents, STEM education has become an educational mode and trend for cultivating comprehensive talents (Bressoud, 2015; Curtis, 2014). There has been a wave of STEM educational research in the world. Moreover, many schools begin to emphasize students' experience of science, and focus on cultivating students' scientific literacy and innovation capacity. STEM education is about the process of producing products and solving real-world problems through activities of engineering design (Kelley and Knowles, 2016). STEM courses integrate the knowledge of multiple disciplines, which enable students to understand science, technology, engineering and mathematics in the process of project-based learning and exploration. Specifically, STEM education emphasizes the use of creativity in the production of products (Hathcock et al., 2015). In this process, students use divergent thinking, convergent thinking and critical thinking to solve problems. They also collaborate to explore and analyze data to produce products. Therefore, one main goal of STEM education is to cultivate students' creativity (Lou et al., 2017), and development of innovative literacy is an important indicator of STEM education (Judson, 2014).

Creativity

Creativity is a primary driving force for individual and social development (Guilford, 1950). Creative thinking is the core of creativity. The cultivation of creative thinking is one primary goal for education (Hu et al., 2010a,b; Lin et al., 2003). Originality and usefulness are two key characteristics of creative thinking (Stein, 1953; Hennessey et al., 2010). In the process of creative thinking, individuals must give up the general method, break the original thinking sets, and think in a unique way (Stein, 1953; Runco and Jaeger, 2012). Creative thinking consists of divergent thinking and convergent thinking (Guilford, 1950, 1967). Divergent thinking is the process of generating multiple answers from different directions to an open question (Sternberg, 1999). Convergent thinking is the process of creatively generating correct answers from given information.

The measurement of creativity is the foundation of research on creativity. Most creative tests are domain-general. According to categories of creativity, the related tests can be divided into divergent thinking tests and convergent thinking tests (Sternberg, 1999). Divergent thinking tests are generally presented in the form of open questions, requiring participants to list as many answers as possible. Divergent thinking tests include Torrance Tests of Creative Thinking (TTCT; Torrance, 1965), Alternate Use Task (AUT),

the Instance Task, and the Consequence Task. The AUT task is to come up with as many novel uses for conventional objects (such as bricks) as possible (Fink et al., 2009; Fink and Benedek, 2014). The Instance Task is to list novel items in common categories (Silvia, 2011). The Consequence Task is to imagine a novel result that might occur in a virtual situation (Silvia, 2011). A convergence thinking test requires individuals to integrate and process target-related information through cognitive processes such as remote association, thinking reorganization, and prototype inspiration (Mednick, 1962). The convergent thinking tests include Remote Association Test (RAT) and Insight Problem Solving. The RAT is to come up with a word (e.g., candle) that can be combined with three unrelated words (e.g., light, birthday, wax) or words that have semantic associations (Mednick, 1968; Mednick and Mednick, 1967). Insight Problem Solving involves an experience of “Aha” feeling at the moment of problem solving. The classic insight problems include the candle problem (Duncker and Lees, 1945) and the Matchstick problem. Tests related to creativity also include self-evaluation or evaluation of personality traits or behaviors such as Creativity Achievement Questionnaire (Carson et al., 2005), Williams Creativity Scale (Williams, 1979). The measurement of creativity has contributed to the development of creative research.

Creativity in STEM education: scientific and technological creativity

Creativity is one of important educational goals (Bermejo et al., 2016). Education is an important way to cultivate students' creativity, especially the STEM education because STEM education can stimulate students' curiosity and focus on inquiry and the cultivation of critical thinking (Henriksen, 2014). STEM education encourages students to use interdisciplinary knowledge and methods to solve real situation problems and unify scientific inquires, technical productions, engineering designs and mathematical methods, aiming at improving students' scientific literacy and innovation ability.

Creativity is not only domain-general, but also domain-specific. Knowledge and skills in a specific field are main components of creativity. Many studies have emphasized that creative thinking requires specific domain or subject-based knowledge and skills (Amabile and Gryskiewicz, 1987). Especially in the fields of STEM (Science, Technology, Engineering, Mathematics), creativity involves the process of using information to produce novel products during solving scientific problems (Amabile, 1996; Hu and Adey, 2002). This process is called scientific creativity (Hu and Adey, 2002; Liang, 2002). Creative products of science and technology generated in STEM or science courses generally have less social value but more personal development value. During STEM learning, the creativity of science and technology is embodied in putting forward novel scientific problems, mastering scientific knowledge profoundly, transferring the mastered scientific knowledge to new situations, discovering unique methods to solve a certain problem, improving the experiment in textbooks, and producing a novel product in activities (Koray, 2003).

Hu and Adey (2002) proposed a three-dimensional Scientific Creativity Structure Model (SCSM), which emphasizes that the measurement of scientific creativity should consider the creative process, trait and product. The process involves designing products through divergent and convergent thinking, and the evaluation of scientific creative products according to the fluency, originality and flexibility of creativity. The products include not only creative outcomes and technical products, but also scientific knowledge gained by individuals and the findings and solutions of scientific phenomena and problems. According to this model, scientific and technological creativity can be demonstrated through observation of scientific phenomena, teaching of scientific knowledge, scientific problem solving, scientific inquiries and creative activities. Individuals can improve scientific and technological creativity by developing creative thinking and creative imagination.

There are several aspects to consider when studying scientific creativity. Different from artistic creativity, scientific creativity involves creative scientific inquiry, creative scientific problem finding and solving, and creative scientific activities. Scientific creativity does not include non-intellectual aspects, although non-intellectual aspects may affect scientific creativity. Scientific creativity relies on scientific knowledge and skills. The structure of scientific creativity reflects the main aspects of scientific creativity, which can guide the measurement, development and research of scientific creativity and the cultivation of young people's scientific creativity.

Researchers have studied ways and techniques to improve creativity (Hu and Adey, 2002; Liang, 2002; Ayas and Sak, 2014). Based on the structural model of scientific creativity and the Torrance Tests of Creative Thinking, the Scientific Creativity Test was developed (Hu and Adey, 2002). The test includes seven open-ended questions to assess students' scientific creativity. For example, one question is “Please write down as many scientific uses of a piece of glass as possible” (Hu and Adey, 2002). Students need to combine the scientific characteristics of glass to answer this question through divergent thinking. The test includes seven abilities or dimensions: creative object application ability, problem solving ability, product improvement ability, imagination ability, problem solving ability, experimental design ability, and technical product design ability. All the questions are open-ended, affording the fluency, flexibility and originality of the subjects' thinking and imagination in the process of answering the questions. Combining scientific creativity with problem finding, the Creative Science Problem Finding Test was also developed (Hu et al., 2010a,b). This test has two questions. One is open-ended, requiring subjects to find questions based on their daily life experience. The other is close-ended, asking subjects to find questions based on a picture of an astronaut standing on the moon. The Technical Creativity Test was also developed to explore the use of technical knowledge and skills by individuals to produce innovative products (Hu et al., 2011).

Development of adolescents' creativity in STEM education

The development of individuals' creativity is closely related to the development of individuals' cognition. In general, creativity increases with the increase of cognitive abilities. Many studies have explored the cultivation of individuals' creativity (Hu et al.,

2004; Kleibeuker et al., 2013a,b). The age trend of creativity, especially the development of creativity in adolescence, has attracted the interest of many researchers. The peaks and valleys in the development of creativity have also been the focus of research.

The development of individuals' scientific creativity of adolescence is a complex dynamic process, which is influenced by various factors. One study compared the developmental trends of scientific creativity among scientific creativity of Chinese and English adolescents (Hu et al., 2004). Chinese and English adolescents are exposed to different cultural backgrounds and educational systems. Culture, social environment, family education, science courses, science teaching, science teachers, and examination methods all have an impact on the development of young people's scientific creativity, which may lead to differences in the development of young people's scientific creativity in China and England. Specifically, teenagers in China and England were assessed using the Scientific Creativity Test. The results showed that the developmental trends of scientific creativity among Chinese and English teenagers was similar. Eleven to 13 and 14–16 years old are the critical periods for the rapid development of adolescents' scientific creativity. Adolescents' scientific creativity in these two stages show a continuously rising trend. At the age of 14, however, other dimensions of scientific creativity performance of adolescents show a decreased trend. At the age of 15, the scientific creativity of adolescents increases again. Adolescents' scientific creativity stabilizes at the age of 17.

With the growth of age, as adolescents master more technical knowledge and accumulate creative experience, their thinking ability and imagination ability gradually develop. Studies have suggested that domain knowledge and skills are a major factor affecting creativity (Amabile, 1983; Feldhusen, 1995). Therefore, with the accumulation of knowledge and experience, the creativity of teenagers is on the rise from the ages of 11 to 13 and 14 to 16 (Smith and Carlsson, 1983, 1985, 1990). This finding is consistent with other research studies (Claxton et al., 2005; Kleibeuker et al., 2013a,b). Claxton et al. (2005) examined the development of creativity of students in grades 4–9 through a longitudinal study. The results indicate that the students' graphic creativity in grade 9 is better than that in grade 6. Kleibeuker et al. (2013a,b) examined the development of the divergent thinking and convergent thinking abilities of individuals in four age groups (12–13, 15–16, 18–19, and 25–30). The results indicate that the performances of 18–19 and 25–30 years old groups are better than that of 12–13 and 15–16 years old on the insight problem-solving task. The 25–30 years old group performs better than 12–13 and 15–16 years old groups on verbal tasks of divergent thinking. The age of 15 is the peak time of development in visual space of divergent thinking.

There is a "low tide" in creative development at the age of 14. This is consistent with previous research (Cheung et al., 2004; Torrance, 1962; Lau and Cheung, 2010) which has indicated that the development of creative thinking from children to adults does not rise smoothly, but increases in a curved manner. There are a total of four lows, which are at 5 years old, 9 years old, 13 years old and 17 years old. Adolescents tend to be sensitive to pressures of social conventions during the transition period of their physical and mental development (Evans, 2006). The age of 14 is a time of transition from adolescents to youth, during which their logical thinking skills transition from experiential to theoretical (Larson, 2000). During this time, adolescents are easily affected by pressure from society, schools, teachers, and peers and feel unsafe and unreliable. This feeling may inhibit creativity by limiting divergent thinking. Another reason is that teachers do not pay much attention to the training of divergent thinking ability (Lau and Cheung, 2010). While logical thinking develops with age, divergent thinking, an important component of creative thinking, has not improved.

The scientific creative ability of 17 years old tends to stabilize. At this age, most of the thinking abilities and mental characteristics of adolescents have matured. In addition, 17 years old adolescents have clear learning motivation, stable learning strategies and personality characteristics. Therefore, the strong cognitive abilities of 17 years old lay the foundation for a steady stream of scientific creativity. The stable cognitive abilities of 17 years old adolescents provide the impetus for the development of their scientific creativity (Hu et al., 2004).

There is also a gender differences in scientific creativity. The performance of males is better than females in scientific creativity, especially in scientific problem-solving, spatial visualization and technical design. This finding is consistent with previous research results (Lau and Cheung, 2010; Alfonso-Benlliure and Santos, 2016; Lau and Cheung, 2015). Lau and Cheung (2015) examined gender differences in the variability of creativity distribution. The results indicate that the variability of the graphic creativity of boys in grades 1–9 is greater than that of girls, but the difference in verbal creativity is not significant. In the process of dealing with problems, adolescent females are more likely to be constrained by mindset than young men (Lau and Cheung, 2010). Adolescent males tend to focus on understanding and exploring problems and adopt unique strategies when facing difficult problems.

In short, the adolescent stage is the peak period for the development of scientific and technological creativity. Science and STEM education can significantly improve the scientific and technological creativity of adolescents. At the adolescent stage, students learn and master subject knowledge, problem solving skills and cognitive strategies. In addition, the adolescence stage is a critical period for the formation and development of self-identity (Arnold, 2017). The practical need for adolescents to apply STEM knowledge stimulate the maintenance of their self-identity. Therefore, in the adolescent stage, the rapid development of knowledge and cognitive abilities promote the development of creativity, leading to high performance in STEM learning for students.

Factors affecting creativity in the educational environment

According to the development trend of adolescents' creativity, the level of creativity is not fixed, but develops with the growth of the individual. Many cognitive factors such as domain-related skills, metacognition and motivation can promote the development of creativity through the influence of education and environment. Current studies focus on the factors that influence creativity in the educational environment. Many studies used the methods of behavioral science, cognitive neuroscience and educational

experiments to investigate the influence of students' internal factors and external factors on the cultivation of creativity in the educational environment (Lin et al., 2003; Hu and Han, 2006). In STEM education, the external environmental factors that affect the development of students' creativity include educational environment, teaching style, peer interaction, emotion and motivation. The internal individual factors that affect the development of students' creativity include knowledge, personality, cognitive inhibition and information processing speed.

Educational environment

Environmental factors that affect creativity can be divided into family environment, school environment and teaching environment. Family plays an important role in the development of the individual (Conger et al., 2010). Feldman (1999) has pointed out that parents' occupation, income, children's birth order and family religion are all factors that lead to differences on the performance of creativity. MacKinnon (1978) studied creative architects and found that their parents have some common characteristics. For example, parents give their children sufficient understanding and respect to allow them to live independently. At the same time, children feel supported from their parents. Baumrind (1991) classified family parenting styles into four types: authoritative, authoritarian, indulgent, neglecting. When parents adopt the authoritative parenting style, their children's creative performance will be better than those who adopt the authoritarian parenting style (Snowden and Christian, 1999).

The school environment affects the ability of creative scientific problem-finding by affecting the creative personality trait (Li et al., 2010). Openness is positively correlated with students' creative scientific problem-finding ability. Especially in the school environment, a good relationship between teachers and students can enhance the positive relation between openness trait and creative scientific problem-finding ability. In the class environment, the teaching environment that provides free discussion can promote the development of creativity. While the teaching environment where the teachers are in control and have too many institutional constraints can inhibit the development of students' creativity (de Souza Fleith, 2000). Besançon and Lubart (2008) have found that an open and democratic learning environment are more conducive to cultivating students' creative thinking than the traditional teaching learning environment. Research has also found that creativity can only be inspired in an atmosphere of tolerance and freedom (Kim, 2005). Moreover, STEM teaching in the laboratory is more conducive to the cultivation of creativity than in the classroom (Chanthala et al., 2018). In STEM teaching environment, the laboratory provides more real learning resources than the ordinary classroom, and promotes students' problem awareness and operation ability, so as to obtain more creative outcomes.

Teaching method

Teaching methods can also affect the development of students' creativity (Hu, 2015). The teaching methods usually include traditional Lecture-based teaching (LBT) and Inquiry-based teaching (IBT). LBT usually follows a subject curriculum. Each subject has a fixed structure and sequence, and uses standard textbooks (Jayawickramarajah, 1996). IBT is a teaching method that combines advanced questioning, student-centered discussion and discovery of central concepts through laboratory activities (Damjanovic, 1999; NRC, 1996). IBT focuses on students' critical thinking, practical ability and problem-solving ability (Kitot et al., 2010). Teaching research has suggested that the combination of LBT and IBT can enhance the teaching effect and improve the academic performance of students in chemistry (Shen, 2009) and politics (Zhou, 2012) subjects. In a study comparing the effects of different teaching methods on students' performance of creative scientific problem finding (Jia et al., 2017), it was found that the mixed teaching method combining LBT and IBT is better than the single LBT or IBT, especially in the dimension of flexibility and originality.

Peer interaction

In STEM teaching, peer interaction plays an important role in group creativity. The establishment of appropriate peer interaction groups can enable peers to share high-level thinking and learning outcomes and promote the development of students' critical thinking (Guiller et al., 2008; Han et al., 2013). Han et al. (2013) examined the effect of peer group types on the scientific creative problems finding at different levels of material learning. Interaction groups were divided into homogeneous group, heterogeneous group, and voluntary group. The results showed that after learning the low-difficulty materials, the students in the homogeneous group performed better on the scientific creative problem finding task than those in the voluntary and heterogeneous group. After learning the high-difficulty materials, the students in the voluntary group performed better than those in the homogeneous and the heterogeneous groups on the scientific creative problem finding task. This may be because the students in the voluntary group have a positive emotional state and a high willingness to cooperate. In addition, there may be an impact of peer ideas and openness on creativity in online collaborative teamwork (Pi et al., 2019a,b). Students with higher openness would pay more attention to novel ideas and be more creative when they were exposed to high percentage of original ideas from their peers. Above findings suggest that teachers should encourage students to share more of their own original ideas and pay more attention to the ideas of peers in online collaboration groups.

Emotion

Emotion is also an important factor that can affect creativity. Studies have found that positive emotions are conducive to scientific creative performance, and negative emotions hinder scientific creative performance (Abele-Brehm, 1992; Chen et al., 2016; Lyubomirsky et al., 2005; Isen, 2008). Positive emotions can improve individuals' cognitive flexibility and avoid the input of irrelevant or

extra information (De Dreu et al., 2008). However, research on convergent thinking has found the opposite result. Negative emotions can promote insight problem solving through cognitive persistence compared with positive emotions (Li et al., 2013). It was further found that current processing types regulate the influence of emotion on the insight problem solving (Li et al., 2020). The primed global processing expands individuals' attention scope. In this case, the negative emotion enables the individual to focus on the current problem by inhibiting the interference of irrelevant stimuli, thus promoting the insight problem solving. Primed local processing reduces the scope of attention. In this case, positive emotions promote insight problem solving by promoting defocused attention.

Motivation

Motivation is an important source of students' learning behaviors and can affect the creative performance (Feldhusen, 1995; Eisenberger and Shanock, 2003). Motivation can be divided into internal motivation and external motivation (Plant and Devine, 1998). Internal motivation focuses on the individual's attention and interest to the activity itself, while external motivation focuses on external rewards and guidance (Collins and Amabile, 1999; Levesque et al., 2010). Research investigated the influence of internal and external motivation on the finding of creative scientific problems (Hu and Zhou, 2010). Results indicate that internal motivation promotes the finding of creative scientific problems through positive incentives, which impacts the fluency and originality. There is an interaction between external motivation and the ability of creative scientific problem finding. The external motivation to expect the positive evaluation has no influence on the performance of creative scientific problem finding, but the external motivation to avoid the negative evaluation has a significant inhibiting effect on the performance of creative scientific problem finding.

Knowledge

Internal factors that affect the development of creativity include knowledge, personality, cognitive inhibition, information processing speed. Domain knowledge is one of the main factors affecting creativity. Without domain knowledge, it is impossible to achieve creative outputs (Amabile, 1983; Feldhusen, 1995). Mastery of a great deal of knowledge is a basic condition for creation, but creation is also affected by the quality of knowledge mastery (Weisberg, 1999). Research in education usually uses the knowledge visualization method (concept map) to explore the knowledge structure of students (Brinkmann, 2003). Flower and Hayes (1984) found that when organizing information and materials, many writers used concept mapping strategies to carry out "brainstorming", which helped them to be highly active during thinking. Riley and Åhlberg (2004) found that concept mapping tasks promote students' creativity.

Differences in scientific creativity performance of individuals with different knowledge structures was investigated (Hu and Zhang, 2007). It was found that there is a significant positive correlation between concept mapping performance and scientific creativity. The nodes of the concept map are significantly correlated with the fluency, originality and flexibility of scientific creativity. This study has also examined the process of students using knowledge to create. First, learners retrieve theme-related information in long-term memory in order to come up with as many concepts as possible. Then, learners need to detect the connection patterns among the retrieved information. Finally, they establish reasonable and novel connections between concepts. In addition, the type of knowledge is also important. Curriculum type also has an influence on students' scientific creativity (Cotabish et al., 2013). Innovative science and technology courses can promote the cultivation of creativity (Cotabish et al., 2013). Innovative science and technology courses focus on design, production and creative applications. Such courses can promote students' advanced cognition and innovation through the application of STEM knowledge.

Personality

Both individual factors and situational factors affect the generation of creative ideas (Amabile, 1996). Therefore, individuals' different personality characteristics cannot be ignored (Barron and Harrington, 1981; Mumford and Gustafson, 1988). Studies on the relationship between personality and creativity mainly use the personality theory to explain creativity, examine personality characteristics of famous people, and investigate the special personality characteristics that may be related to creativity. One study analyzed seven personalities that are highly related to creativity out of 38 personality structures (Martinsen, 2011). The seven personality types are: need for originality, flexibility, instability, ambition, agreeableness, associative orientation and motivation. Moreover, a study explored the relationship between school environment, students' personality traits and the ability of creative scientific problem finding. The results indicate that the openness personality significantly predicts the ability of creative scientific problem finding. High openness individuals tend to be curious, imaginative and receptive to new ideas, thus they perform better in scientific creativity (Li et al., 2010).

Cognitive inhibition

A large number of studies have found that individuals with high creativity show variable attention and flexible cognitive inhibition (Vartanian et al., 2007; Zabelina and Robinson, 2010). A study explored the differences in cognitive inhibition between individuals with high and low levels of ability on scientific creative problem solving (Bai et al., 2014). The result indicates that individuals with high creativity could freely switch between focused attention and defocused attention to realize the flexible allocation of attention

resources. When interference information is presented, high cognitive inhibition ability of individuals with high scientific creativity can flexibly shift their focus of attention at different stages of problem solving. Furthermore, there is a relationship among cognitive style, cognitive inhibition, and scientific creativity (Cheng et al., 2016). The results suggest that cognitive style plays a mediating role in the relationship between cognitive inhibition and creative scientific creativity. The influence of cognitive style on creative scientific problem finding is modulated by external cues. Individuals with strong cognitive inhibition have a strong tendency of field independence in information processing and a weaker dependence on external heuristic information, so that they can more effectively use heuristic information to reduce processing load. On the contrary, individuals with weaker cognitive inhibition show a strong tendency of field dependence, and are more susceptible to the influence of irrelevant stimuli in information processing, which can lead to poor performance on scientific creative problem finding.

Information processing speed

Information processing speed is an important indicator of an individual's mental ability (Luciano et al., 2001). It refers to the number of tasks completed within a specified time. The information processing speed also affects creativity. During cognitive processing, learners with fast information processing speed are more actively thinking and are more likely to solve problems through insight (Hu et al., 2010). Compared with students with low creativity, students with high creativity process information more quickly (Silvia et al., 2013). In the process of thinking about new scientific ideas, interference information plays a moderating role in the relationship between creativity and processing speed (Dorfman et al., 2008; Vartanian et al., 2007). When interference information needs to be suppressed, scientific creativity is significantly positively correlated with processing speed (Hu et al., 2010). In the absence of interference information, there is a significant negative correlation between scientific creativity and processing speed.

Cultivation of creativity in STEM education

In STEM education, students' innovation literacy is usually cultivated in the following ways: project, curriculum and classroom teaching. Project training refers to project activities can be carried out at the national or school level to promote students' scientific inquiry and innovative literacy. Students can experience the fun of scientific creation, improve their curiosity and scientific motivation, and develop divergent and critical thinking. Curriculums can support the development of students' creativity (Hu, 2015). Some studies have indicated that the activity curriculum aims at cultivating students' thinking ability is effective (Hu, 2015; Cornelius-White, 2007). On the one hand, students can learn thinking methods through activity courses. On the other hand, thinking training integrated with curriculum knowledge helps students to acquire knowledge and learn to apply and transfer knowledge. Innovative classroom teaching is also an important way to cultivate students' creativity. Classroom teaching that promotes creativity has four key characteristics: learning motivation, cognitive conflict, social construction, self-monitoring, application. In the process of teaching, teachers need to set up cognitive conflicts to arouse students' motivation. Students explore, summarize and reflect through interaction, gain knowledge through operation and learn to transfer knowledge to solve practical problems.

Cultivation of creativity through projects

STEM teaching can be integrated into basic education courses, or combined with students' life to develop separate STEM curriculums. These STEM teaching strategies promote students' single-subject knowledge, creative motivation, and practical innovation ability in complex learning situations. Specifically, a large number of STEM schools have been established. These schools pay particular attention to creation of new courses and cultivation of high-level thinking skills by offering research-based learning activities for students (Atkinson and Mayo, 2010; Gonzalez and Kuenzi, 2012). PLTW (Project Lead The Way) has been developed (Project Lead The Way, 2018) in order to promote the training of students in STEM fields. PLTW has created a continuous pathway of education from secondary education to college in STEM fields. PLTW is a question-based course designed to increase interest and knowledge in mathematics, science and engineering. The MSIP (Mars Student Imaging Project) aims to encourage educators and students to participate in and experience professional NASA scientific research and engineering technology activities in real or simulated environments (Klug and Christensen, 2001). MSIP provides an authentic platform for students to practice science. Students can propose hypotheses, identify research topics, conduct surveys, collect and analyze data, solve problems, and communicate with Martian scientists. MSIP not only promotes the teaching of traditional subject knowledge, but also provides students with the opportunity to participate in the creative process that is closely related to reality.

"Spring shoot project" aims at cultivating creative talents jointly between universities and middle schools (Hu, 2015). The plan includes selecting middle school students with creative potential to go to the university laboratory to participate in research projects. So far, the selected students have carried out 33 projects in engineering applications, transportation, electronic technology, aerospace, nanotechnology, environmental engineering, network and so on, and have won many awards. It has been found that these students' creativity has significantly improved. This project has not only cultivated students' innovation ability, but also developed a group of research-oriented middle school teachers, who have begun to pay attention to and encourage students who have unique ideas in class. Schools have also begun to emphasize the importance of practice, encouraged interaction and cooperation between the students.

Cultivation of creativity in STEM education

Students' scientific and technological creativity can be cultivated through education. One goal of STEM education is to cultivate students' innovative literacy, so that it can promote the development of creativity beyond conventional education. The cultivation of students' creativity in STEM education can be carried out from four aspects: individual, environment, process and strategy.

Individual

STEM education can cultivate students' personality traits, such as curiosity, inspiration, independence and critical thinking. Studies have shown that personality traits have a significant predictive effect on the generation of creative ideas (Eysenck, 1993; Prabhu et al., 2008). The interdisciplinary and situational characteristics of STEM education play an important role in supporting the cultivation of students' scientific and technological creativity. STEM education is based on real world problem solving and emphasizes the integration of knowledge and skills in science, technology, engineering and mathematics. This can help students break the knowledge barrier caused by traditional subject-based education and learn to understand the world from a systematic perspective. The learning of interdisciplinary knowledge can promote the accumulation of students' experience, thus improving the thinking flexibility, enhancing the association between different ideas, and overcoming the functional fixation (Moirano et al., 2020). STEM education is based on problem or project-based learning. Therefore, STEM activities stimulate students' motivation and help them solve problems in creative ways by designing activities that promote knowledge integration and transfer.

Environment

STEM teaching environment mainly includes learning atmosphere, teacher-student relationship and teaching resources. The studies have indicated that creative classroom atmosphere, democratic teacher-student relationship, harmonious collaboration between the students, and abundant educational resources play an important role in supporting the development of creativity (de Souza Fleith, 2000; Cornelius-White, 2007). On the one hand, STEM teaching emphasizes that teachers should organize and inspire students strategically to build exploratory and challenging teaching content for students and encourage a creative classroom atmosphere. On the other hand, collaborative inquiry learning in STEM education stimulates students' engagement, which promotes the exchange of ideas among students. This process is conducive to the construction of collective knowledge and the development of creative thinking. In addition, STEM education usually relies on experimental environments equipped with advanced teaching tools, abundant resources and creative atmosphere. In such an environment, students are more likely to creatively solve problems in multiple ways and share their creative ideas. Therefore, this environment also promotes the development of students' scientific and technological creativity.

Process

STEM teaching process mainly refers to activity design, teaching method and evaluation method. Creative activity design and teaching methods can provide an effective path for the development of creativity (Kolodner, 2002). Most of the activity designs of STEM teaching are project courses based on problem solving (Capraro et al., 2013). Problem-oriented STEM learning can help students connect knowledge with real-world problem situations and learn knowledge in the process of solving real-world problems (Parker and Lazaros, 2014). Moreover, another characteristic of project-based STEM courses is the integration of interdisciplinary knowledge. An important goal of STEM learning is the construction and learning of interdisciplinary concepts. Students should not only acquire the core knowledge of the subject, but also learn the common concepts that connect different subject areas. Research has indicated that interdisciplinary STEM activities can help students better understand subject concepts (Fulton and Britton, 2011). Teaching methods are also an important factor in cultivating students' scientific and technological creativity. Rogers et al. (2015) have proposed a teaching model that uses continuous themes and a multidisciplinary approach for interdisciplinary integration. This teaching model not only retains the advantages and contents of traditional courses, but also helps students solve real problems in real life. This teaching method that combines traditional curriculum content with real problems promotes students' creative problem solving.

In addition, studies have emphasized the role of teachers in project-based STEM learning (Fosnot and Dolk, 2001; Mehalik et al., 2008). STEM activities require teachers to design activities from concept to behavior based on course content. In the teaching process, teachers encourage students to work together as groups (Puntambekar and Kolodner, 2005). This may increase students' creative activities and promote the development of STEM skills for problem solving. Saxton et al. (2014) have designed a STEM common measurement system to evaluate the development of STEM education from four aspects: student learning, teaching practice, teacher professional development and school support. Studies have explored the impact of learning goals and performance standards set by teachers in classroom learning on diagnostic teaching (Webb and Jones, 2009).

With more diversified methods, evaluation of students' innovation ability is also included in the evaluation system (Juliantari et al., 2018; Keinänen et al., 2018). STEM education connects the learning and application of scientific, technological, engineering and mathematical concepts, emphasizes the use of scientific inquiry to explore the unknown things and phenomena, and promotes the creative design (Bequette and Bequette, 2012; Honey and Kanter, 2013). This process is not only the process of solving problems, but also the process of generating creative ideas (Guilford, 1959).

Strategies

The strategy part mainly refers to creativity training methods and the cultivation strategies. Creativity training includes brainstorming and thinking training methods. Creativity cultivation strategies include creating problem situations, stimulating students' interest, setting cognitive conflicts and assigning open tasks (Hu, 2015). The characteristic of STEM teaching is to emphasize students' design ability and problem solving ability in complex situations. Many studies have explored the learning strategies in STEM teaching (Mayo, 2009; Smith et al., 2009). Apedoe et al. (2008) used design-based learning to integrate engineering design and scientific inquiry to help students learn chemical concepts. Mayo (2009) analyzed the impact of game-based learning on creativity. Although researchers try to use different teaching methods to study STEM teaching strategies, problem-based learning and project-based learning are currently two most commonly used teaching methods in STEM education (Barell, 2006; Capraro et al., 2013). Project-based learning in STEM education focuses on the situational characteristics of the problem and stimulates students' design orientation (Kennedy and Odell, 2014). Research has indicated that this teaching strategy can promote students' cooperation and promote the implementation of creativity training and cultivation strategies (Kennedy and Odell, 2014). Specifically, project-based learning strategies can guide students to generate a variety of ideas or inspirations through accessing original experiences to solve problems and promote the production of creative outcomes (Parnes, 1987). Meanwhile, students gain experience in the process of practice, along with the review, thinking and insight of knowledge and experience. Research has found that in the process of engineering design, brainstorming and collaboration among team members, cognitive differences among members are conducive to the generation of creativity (Wang et al., 2011).

Future research prospects

Developing effective STEM curriculums

The focus of STEM courses is to promote the application of knowledge and the transfer of skills. The engineering and technical disciplines emphasize the application of skills by students. However, STEM courses and teaching that emphasize the use of technical tools may limit the depth and multidisciplinary integration of STEM content, making students only have shallow learning and fail to achieve deep learning. STEM education is not simply a combination of science, technology, engineering, and mathematics, but an effective integration of them. In real-world problem-solving, students gain knowledge through practice and application (Fortus et al., 2005). Studies have shown that due to the interdisciplinary characteristic of real-world problems, adopting this interdisciplinary learning approach in solving real problems can promote the understanding of STEM concepts. Therefore, future research should develop STEM courses that promote knowledge integration and break the disconnection between STEM disciplines and with other non-STEM disciplines. In addition, future research should integrate interdisciplinary learning methods into basic education courses to effectively conduct interdisciplinary STEM learning activities.

Specifically, the integrated curriculum should emphasize the application of knowledge and focus on the relationship between disciplines. The construction of STEM course resources should emphasize the "problem context" and the authenticity of the context. Context and problem are the key to the integration and connection of interdisciplinary knowledge. Real context problems help develop the ability of knowledge transfer for students.

Importantly, introducing real-world problems into the STEM curriculums and enabling students to explore knowledge in practical activities to solve real-world problems can promote students' creative problem-solving ability (Hu, 2015; English and Mousoulides, 2015). Moreover, STEM courses should set up situational activities that promote the cooperation and interaction among students and encourage students to be active, which can provide a positive environment for the construction of knowledge. Studies in STEM education should develop feasible courses based on the local economic and cultural characteristics. Such STEM courses will give students a sense of achievement, make them realize the close connection between STEM education and life, and enhance their learning motivation. In addition, it is necessary for future research to construct STEM courses with the core teaching goal of cultivating creativity. In terms of teaching goals, more attention should be paid to basic knowledge and creativity. Basic knowledge goals are related to the STEM project theme. Creative performance can be measured from three aspects: creative consciousness, creative thinking and creative products. Creative performance can be promoted through the learning of interdisciplinary knowledge in STEM courses.

Exploring effective STEM classroom teaching

Classroom teaching is the basic organizational form of school teaching and the main way of quality-oriented education and cultivating students' creativity. Herschbach (2011) has indicated that activities are an effective form of organization for STEM courses. STEM courses generally focus on projects, tasks or problems. During STEM learning, students need to solve problems or complete project tasks through learning activities one by one. These activities can connect the learning content with the real world. Students complete these activities through cooperative and practical learning. The completion of these activities can promote deep learning of students and cultivate their awareness and ability of learning.

However, in STEM teaching, the roles of students and teachers may be ambiguous, and the rules of teaching activities may not be clear, which could lead to inappropriate intervention of teachers in the process of teaching, as well as disorderly teaching patterns in the classroom. This is not conducive to the achievement of students' learning goals, and thus unable to effectively achieve the teaching goals. Future research should explore more effective forms of organization of teaching activities. In addition, future

research should develop more effective teaching activities, and analyze behaviors of teachers and students in the process of activities, as well as the interaction and communication between students. Future research should also explore the influence of teaching activity organization on students' creative problem-solving ability by focusing on groups and individuals.

Specifically, future research should explore the impact of teaching methods in STEM education on students' scientific and technological creativity. STEM education mainly adopts the following teaching methods: project learning, lecturing and discussion. Project learning is a method for students to build knowledge through teamwork. Factors such as project-based learning materials, relevance of the project to students, complexity of the project, provision of appropriate support, prior knowledge of students and teamwork ability will all affect the learning of the project. In studying STEM subject contents, students not only need to collect relevant materials for learning, but also need to be guided by teachers through lecturing. Providing instruction through lecturing is particularly important for students in lower grades. Future research should explore the use of various teaching methods and explore the optimal combination of teaching methods for cultivating students' creativity. In addition, future research should explore the relationship between teachers and students in the teaching process. Traditional teaching activities are mainly led by teachers, which is not conducive to students' creative thinking. In the process of solving creative problems, an individual's self-construction process is particularly important. Therefore, future research should explore the influence of teachers' intervention degree on students' self-construction in the teaching process.

Future research should explore suitable teaching contents for students based on STEM courses, such as the balance between practical knowledge and theoretical knowledge. Previous STEM curriculum activities mainly focused on practice. Although such activities could promote the development of students' problem-solving ability, they ignored the underlying principles of behaviors. Therefore, future research should focus on the balance between practical knowledge and theoretical knowledge in classroom teaching. In addition, future research should develop interesting and risky classroom activities to improve students' learning motivation. Scientific learning motivation has the functions of arousal, orientation, selection and reinforcement, and it affects students' psychological processes such as observation, memory, thinking, imagination and problem solving. It also affects the development of students' scientific and technological creativity (Bhakti et al., 2018). In science teaching, students' motivation to learn science should be stimulated by setting up problems and connecting science teaching with real world.

Constructing innovative and operational evaluation system for STEM education

There are two research directions for STEM educational evaluation. The first one is to conduct STEM education evaluation research through specific thinking ability cultivation (Lin et al., 2015). The second one is to construct the educational evaluation system according to the subject curriculum (English and King, 2015). The evaluation of STEM education that adopts the relevant curriculum model is mostly based on the curriculum standards of science, mathematics, and technology. However, the STEM teaching evaluation model that aims at the cultivation of thinking ability does not have a unified standard for reference. Moreover, the current evaluation of STEM education is based on a single measurement standard; it does not have a clear measurement goal for learning outcomes, which may not only waste teaching and learning time, but also reduce classroom creativity. It may also limit the development of students with high creative thinking. Educational evaluation should focus on the scientific measurement of students' continuous learning ability, personal literacy, and academic inquiry ability. Therefore, future studies could improve measurement methods to integrate STEM educational evaluation criteria. It is necessary to measure students' mastery of various skills and knowledge in the learning process and to increase the evaluation of students' innovation ability.

Real-time evaluation can help teachers identify meaningful behavioral patterns and thus enable teachers to adjust teaching method according to learning measurement results. The convergence of technology and education could provide new measures for STEM education assessment. Educational games, real-time evaluation and cognitive neuroscience technology are innovations in learning measurement. Future research should develop innovative and operational learning assessment methods and adopt technical measures to support the process of personalized assessment. For example, future research could develop software or programs to measure learning of students, and provide personalized and timely support. For teachers, these software or programs can provide teachers with real-time data on students' learning, and teachers can observe and record students' skills and norms of behavior, thus being able to evaluate students' learning behaviors in specific situations. At the same time, this type of assessment can provide immediate feedback to the teacher, allowing the teacher to provide other support to help students find key points in the learning process. Educational games can introduce students to scientific concepts through a variety of representations and provides real-time assistance (Filament Games, 2009; Herro and Clark, 2016). Educational games such as "Ripple Effects" (Olberding and Olberding, 2010) and "The Social Express" (The Language Express, 2013), which provide virtual environments, are new evaluation means to measure learners' Social ability.

With the development of educational neuroscience, exploring the effects of STEM teaching through brain imaging technology may become a future research trend. Brain imaging techniques such as functional MRI and event-related potentials can be used to explore appropriate learning resources and environments in a scientific way. Previous studies on the evaluation of teaching effect mostly focused on knowledge mastery and lacked systematic evaluation of learning ability, learning process and learning efficiency. Moreover, online learning is becoming more and more popular and has become the preferred way of learning for some students. Through brain imaging technology, the teaching design and learning effects of online learning can be monitored and guided. Educational neuroscience can measure students' learning state, ability, attention and emotion, and reveal the underlying cognitive neural mechanism of teaching effect, which can help teachers understand the internal cognitive state of students in the learning process, thus contributing to the effective control of classroom teaching (Gallistel and Matzel, 2013). In addition, brain imaging technology

can also measure the difference in teaching effect under different teaching methods, which is helpful for teachers to choose appropriate teaching methods in teaching and improve the teaching evaluation system (Bowers, 2016). For example, studies have explored differences in brain activity between high and low academic achievers (Chrysikou et al., 2020). The results showed that there are differences in brain function among students with different academic achievement levels. Therefore, future research can develop teaching evaluation system based on cognitive ability and brain network through brain imaging technology.

Introduction

Researchers (i.e., geographers, astronomers, psychologists and educators) in National Research Council (NRC) argue that spatial thinking is universal and useful in a wide variety of academic disciplines and everyday problem-solving situations (NRC, 2006; NRC, 2013). The researchers also claim that spatial thinking can, and should, be taught at all levels in the educational system (NRC, 2006). The crucial role of spatial thinking has been widely acknowledged in the education field, especially for STEM disciplinary and interdisciplinary teaching and learning - in recent years; a growing number of STEM education research are conducted regarding spatial thinking (e.g., Bodzin, 2011; Jo and Bednarz, 2014; Shin et al., 2016; Sorby, 2009). Supporting by many research findings, a picture of the relationship between spatial thinking and STEM education is gradually emerging.

Past literatures of spatial thinking and STEM education suggest that the relationship between them is mainly two-fold: (1) Spatial thinking is one factor that may influence students' capacity in STEM disciplinary and interdisciplinary learning (Hegarty, 2010; Uttal et al., 2013; Uttal and Cohen, 2012); and (2) Taking well-designed STEM lessons, especially the ones that integrate geo-spatial technologies, could facilitate students' development of spatial thinking. In other words, the relationship between spatial thinking and STEM education is mutual; students' STEM learning and practice require a certain level of spatial thinking ability, meanwhile, doing STEM activities cultivates students' spatial thinking ability.

This article unpacks the above two major relationships between spatial thinking and STEM education by introducing the existing concepts and measurements of spatial thinking (i.e., what is spatial thinking and how to measure it), importance of spatial thinking in STEM learning (i.e., why educators need to draw attention to spatial thinking in STEM education), and the ways of cultivating students' spatial thinking in STEM classes (i.e., how to well-prepare students' spatial thinking development through STEM learning). Through illustrating what, why, and how in spatial thinking and STEM education, I will present several highlights in this research area at the end of the article.

What is spatial thinking?

Existing concepts of spatial thinking

The term "spatial thinking" has been used in both academic and non-academic settings extensively. A variety of definitions of spatial thinking exist in different disciplines. For example, Lohman (1979) defines spatial thinking ability as "the ability to generate, retain, and manipulate abstract visual images" (p. 126), while Schneider and McGrew (2012) define spatial thinking ability as the ability to make use of simulated mental imagery (often in conjunction with currently perceived images) to solve problems (2012, p. 129). Additionally, in geography education, the concept of spatial thinking has a somewhat nebulous

meaning, as various terms, such as “thinking spatially”, “geospatial thinking”, “spatial intelligence”, and “spatial ability”, are used synonymously (Huynh and Sharpe, 2013).

However, the existing concepts and terms either only refer to spatial thinking in certain field which is not a general and representative definition, such as in cognitive psychology and geography fields, or only represent a narrow concept which in fact is one of the many components in spatial thinking (Lee and Bednarz, 2011), such as spatial visualization (Carroll, 1993). Many researchers in this field have reached an agreement that providing a good definition of spatial thinking is not as easy as one would expect (Lee and Bednarz, 2011; Gersmehl and Gersmehl, 2007; Uttal and Cohen, 2012), which also raises a series of questions such as: is there one spatial ability, or are there many? How the different terms regarding to spatial thinking relate to one another? (Gersmehl and Gersmehl, 2007; Uttal and Cohen, 2012). Apparently, a widely accepted, broadly covered, and specific framework of spatial thinking is needed to clearly define a research field.

Spatial thinking framework introduced by National Research Council

Through a multi-year collaboration among experts in different fields, including education, geography, earth science, planetary science, psychology, and cognitive science, a NRC report on Learning to Think Spatially (NRC, 2006) clarifies definitions, concepts, and categories of spatial thinking, and provides a framework of spatial thinking for today’s educational milieu (NRC, 2006). In addition, it examines how spatial thinking could be incorporated into existing standards-based curricula, and emphasizes that spatial thinking must be recognized as a fundamental part of K-12 education, and as an integrator and a facilitator for problem solving across curricula (NRC, 2006). The framework has been widely recognized and applied by STEM educators (e.g., Bodzin, 2011; Lee and Bednarz, 2009; Tomaszewski et al., 2015).

The NRC (2006) defines spatial thinking as the knowledge, skills, and habits of mind to use concepts of space and representations, and processes of reasoning to structure problems, find answers, and express solutions to these problems. They introduce three spatial thinking contexts: life space (cognition in space), physical space (cognition about space), and intellectual space (cognition with space). The report also introduces several ways in which spatial thinking may be characterized (NRC, 2006). For example, spatial thinking can be broken down into different components, such as spatial knowledge, spatial ways of thinking and acting, and spatial capabilities; or concepts of space, tools of representation, and processes of reasoning. It also can be characterized through the differentiation of spatial component tasks, such as extracting spatial structures, performing spatial transformations, and drawing functional inferences (NRC, 2006). The interpretations of the above spatial thinking contexts and categories are presented in Table 1. Thus, it is important to notice that within the framework of spatial thinking provided by the NRC (2006), there is no one way to characterize spatial thinking, and the various characterizations of spatial thinking are all acceptable.

Within the contexts and characteristics of spatial thinking introduced by the NRC (2006), several theories of spatial thinking components have been developed following NRC’s (2006) framework (e.g., Golledge, 2008; Lee and Bednarz, 2011; Janelle et al., 2009). Most of the updated theories and framework are highly related to STEM teaching and learning, which can be regarded as reference for STEM educators. For example, Lee and Bednarz (2011) proposed eight specific spatial thinking components:

- (1) Visually navigating road maps using verbal information, including a participant’s current location, directions to destinations, and street information;
- (2) Recognizing map patterns and representing them in a graphic form;
- (3) Selecting an ideal location for a fictitious facility, based on multiple pieces of spatial information;
- (4) Creating a profile of topography along a proposed line on a contour map and properly orienting it;
- (5) Identifying spatial correlations between sets of maps, and displaying the identified spatial relationship in a graphic form;
- (6) Mentally visualizing a 3D image based on 2D information;
- (7) Visually verifying a map overlay process, and selecting the appropriate maps layers involved in the overlay;
- (8) Visually extracting types of spatial data from verbally expressed spatial information.

In summary, the NRC report (2006) provided an up-to-date definition of spatial thinking, reflecting a wider variety of academic disciplines and everyday problem-solving situations, and aligning with 21st century skills (NRC, 2006; Lee and Bednarz, 2004). NRC’s framework allows STEM educators and researchers accurately locate their position in studying spatial thinking and clarify the relationship between spatial thinking in STEM field and in others.

How to measure spatial thinking?

Assessing students’ and teachers’ spatial thinking ability in STEM field is needed in conducting relevant research. Spatial thinking is complex, and involves elements of interest to both psychologists and geographers (Huynh and Sharpe, 2013). In the field of psychology, a variety of tests have been widely used to measure individuals’ spatial abilities, but the tests in psychology are content general (Lee and Bednarz, 2011). Furthermore, spatial ability is a different concept from spatial thinking and it is a narrower concept than spatial thinking (NRC, 2006). In order to measure spatial thinking as defined by the NRC report (2006), researchers need to go beyond the limits of existing content general spatial tests (Eliot and Czarnolewski, 2007). Thus, only two measurement instruments that align with the NRC’s (2006) framework are discussed in this section, which might be used for STEM educators and researchers to obtain students and teachers’ spatial thinking ability.

Table 1 Interpretations of spatial thinking contexts and categories in [NRC \(2006\)](#).

<i>Categories and terms</i>			<i>Interpretations</i>
Spatial thinking contexts	Life space (cognition in space)		Building on the four-dimensional world of space-time to grip the spatial relations between self and objects in the physical environment.
	Physical space (cognition about space)		Building on the four-dimensional world of space-time with a focus on understanding the nature, structure, and function of phenomena.
	Intellectual space (cognition with space)		Understanding relationships among concepts and objects that are not in and of themselves necessarily spatial, but rather the nature of the space that is defined by the particular problem.
Spatial thinking category examples	Example 1	Spatial knowledge	Concepts such as symmetry, orientation, rotation, scale, relative versus absolute distance, and distance decay.
		Spatial ways of thinking and acting	Recognizing and using the similarity distance metaphor, using diagramming or graphing in problem-solving, recognizing clusters and patterns in data, separating change over space from change over time, knowing how, where, and when to use the various spatial-thinking strategies, and etc.
		Spatial capabilities	The ability to use supporting tools and technologies such as spreadsheet, graphical, statistical and GIS software to aid in problem-solving.
	Example 2	Concepts of space	Such as the relationships among units of measurement, different ways of calculating distance.
		Tools of representation	Such as the understanding of the relationships among views, and the effects of geographic projections.
		Processes of reasoning	Such as the ability to think about the shortest distances in different ways, and to make decisions based on spatial information.

The first relevant instrument is the Spatial Thinking Ability Test (STAT). [Lee and Bednarz \(2011\)](#) conducted a study focusing on the components of spatial thinking in the geoscience domain. In their study, they first reviewed the concepts of spatial thinking introduced in previous studies ([Gersmehl, 2005](#); [Janelle et al., 2009](#)). By reorganizing the core concepts of spatial thinking as introduced in prior studies, they developed the STAT, which contained 16 questions measuring 8 spatial thinking components relevant to geoscience. Examples of STAT questions and spatial thinking ability components present in [Fig. 1](#). The STAT covers spatial thinking components over a wide range ([Lee and Bednarz, 2011](#)). There are two forms of the STAT; they have the same types of question, and measure the same spatial thinking components, but the questions in the two forms are different. Since the two forms of the test are of equal difficulty, they can be used as pre- and post-test in measuring changes in students' spatial thinking ability ([Lee and Bednarz, 2011](#)).

Besides the STAT, [Cohen and Hegarty \(2012\)](#) also designed a spatial thinking test called the Santa Barbara Solids Test (SBST). Rather than focusing on all spatial thinking concepts, the SBST only explores students' spatial skill of cross-section ([Cohen and Hegarty, 2012](#)). The test consists of 30 multiple choice questions; three levels of geometric structure and two types of cutting planes are distributed evenly across the 30 questions ([Cohen and Hegarty, 2012](#)). The results also indicated that "complexity of geometric object being sliced, and orientation of the cutting plane" are two difficult items for students.

A few other questionnaires on spatial thinking exist. However, they are not within the framework that [NRC \(2006\)](#) provides, such as [Dean and Morris \(2003\)](#), and [Hall-Wallace and McAuliffe \(2002\)](#). Other measurement instruments such as [Hegarty et al. \(2002\)](#) are more appropriate for classifying types of spatial behavior, rather than determining levels of student spatial ability ([Lee and Bednarz, 2011](#)).

Why should we consider spatial thinking in STEM education?

Prior studies provided evidence for the idea that spatial thinking is fundamental to the theoretical and practical underpinnings of geography (e.g., [Huynh and Sharpe, 2013](#); [Kim and Bednarz, 2013](#); [Favier et al., 2014](#); [Xiang and Liu, 2017](#)). The nature of the study of geography is to explore the patterns and processes of phenomena on the Earth's surface, at a variety of scales ([Huynh and Sharpe, 2013](#)). Due to the nature of geography, the exploration of the concept of earthly space, spatial thinking is the core ability at play during this process ([Huynh and Sharpe, 2013](#)). However, there is a common misunderstanding that spatial thinking is only important for the study of geography, when in actuality, it is equally important for other STEM subjects, such as science and technology

*DIRECTIONS: Solve the following questions based on the example below. Please mark (v) an answer.
Question #9 and #10 are adapted from Albert and Gollege (1999)*

Spatial Thinking Ability: visually verify a map overlay process and select the appropriate maps layers involved in the overlay (Lee & Bednarz, 2011)

*DIRECTIONS: Real world objects can be represented explicitly by point, line (arc), and area (polygon).
Based on the examples below, classify the followings spatial data.*

5. Locations of weather stations in Washington County _____.

- (A) Lines
- (B) Area
- (C) Points and Lines
- (D) Points and Area

6. Mississippi River channels and their basins _____.

- (A) Lines
- (B) Area
- (C) Points and Lines
- (D) Lines and Area

Spatial Thinking Ability: to be able to visually extract types of spatial data from verbally expressed spatial information (Lee & Bednarz, 2011)

Fig. 1 Examples of STAT questions and spatial thinking ability components.

(Uttal and Cohen, 2012; Wu and Shah, 2004). A comprehensive understanding of students' and teachers' spatial thinking ability, and suggestions on how to improve it, keeping in perspective a variety of STEM disciplines, is needed.

Specifically, research indicates that proficiency in spatial thinking is associated with success in engineering, architecture, medicine, mathematics, and the sciences, and students' spatial thinking ability is correlated with STEM achievement and attainment (e.g., Hegarty, 2010; Uttal et al., 2013; Uttal and Cohen, 2012; Wu and Shah, 2004; Stieff and Uttal, 2015). For example, Uttal et al. (2013) reviewed the relationship between STEM achievement and spatial thinking, and the results indicate that spatial training could improve STEM learning. Wai and Benbow (2010) conducted a 25-years longitudinal study and found that psychometrically-assessed spatial skills are a strong predictor of STEM attainment (Wai et al., 2009).

Moreover, in STEM disciplinary learning, a number of studies indicate the close relationship between STEM content and spatial thinking components (e.g., Hegarty et al., 2009; Uttal and Cohen, 2012; Sorby, 2011). For example, in chemistry, the behavior of isomers has a close relationship with spatial configurations (Uttal and Cohen, 2012); in biology, the understanding of cell structure can be enhanced through spatial visualization (Wu and Shah, 2004); and in physics, solving kinematics problems is also in relation to spatial visualization (Kozhevnikov et al., 2007).

Despite the importance of spatial thinking ability in teaching and learning within a multitude of fields of study, most studies of spatial thinking ability are confined to the subject of geography (Jo and Bednarz, 2014; Shin et al., 2016; Lee and Bednarz, 2009); limit research explored spatial thinking in other disciplines, such as science and technology (Bodzin, 2011; Sorby, 2009). Thus, more research regarding spatial thinking in STEM education field needs to be done in a broader set of disciplines.

High demand versus low performance in students' spatial thinking

The above literatures documented the close relationships between the need for spatial thinking ability and STEM education. Research also indicates that the STEM job market is facing a shortage of geospatially-trained workers (NRC, 2013). Therefore, it is also important that students' spatial thinking abilities are improved so that they are qualified for relevant future work. However, comparing the high demand of students' spatial thinking ability, their actual performance is relatively low, especially for students in K-12 settings. The status of students' current spatial thinking does not allow STEM educators to be optimistic.

Low performance in overall spatial thinking

Previous empirical studies evidenced that students' spatial thinking ability is still relatively low. For example, Bodzin (2011) examined secondary school students' spatial thinking abilities, by testing the three elements of spatial thinking addressed by the NRC (2006): concepts of space, tools of representation, and processes of reasoning. On average, students correctly answered 8 questions out of 18 total questions, amounting to less than a half percent rate of correctness. In addition, using the STAT, Tomaszewski et al. (2015) found that, on average, secondary school students only correctly answered 4 to 5 questions out of 16 total questions; identically, in Li (2020), students also correctly answered 4 to 5 questions with 28% accuracy. It is worth to notice that student participants from Li (2020) were only from urban public secondary schools, which may not represent students from all school settings, such as private schools, or suburban and rural schools. Tomaszewski et al. (2015) found that tested urban school students outperformed tested rural school students. In other words, rural school students might have even lower spatial thinking abilities than do urban school students. Thus, students' overall spatial thinking abilities must be improved, and further research on the status of students' spatial thinking abilities - across various school settings - is needed.

Low performance in spatial components that highly relate to STEM

In order to provide more precise and effective advice on improving students' spatial thinking ability, researchers suggest the importance of studying students' spatial thinking in terms of the different components (Lee and Bednarz, 2004; Li, 2020; Tomaszewski et al., 2015). For example, Tomaszewski and colleagues studied students' spatial thinking abilities according to different components, and their abilities varied. However, some students' low performed spatial thinking ability components are highly in relation to their STEM learning.

For example, Li (2020) found that secondary school students still lacked skills in comprehending overlay and dissolve, mentally visualizing 3-D images based on 2-D information, comprehending spatial shapes and patterns, and solving complex spatial questions with various components; they had better abilities in comprehending orientation and direction, discerning spatial patterns, and comprehending spatial association. In taking a closer look at spatial thinking ability components, it becomes clear that the components for which students exhibited a low ability are actually some of the principal components required in STEM interdisciplinary learning at the secondary level. For instance, transforming perceptions, representations, and images from one dimension to another, and the reverse, is one of the important spatial thinking abilities that is frequently used in students' science, math, and technology classes. To understand a certain concept or features of a subject, students are often required to transfer a 2D graph or picture to 3D, such as in learning about cellular structure in biology, molecular structure in chemistry, the earth's rotation and revolution in earth science, and solid geometry.

Furthermore, STEM researchers and educators also need to notice that during STEM disciplinary learning and everyday problem-solving situations, students usually encounter questions which require more than one spatial thinking ability component to solve. For example, in the STAT, students were asked to produce the image of a slope profile based on a topographic map, which requires the spatial thinking ability of recognizing spatial form, being able to transform perceptions, representations and images from one dimension to another and the reverse, and graphing a spatial transition. However, working on complex spatial thinking problems

requires strong spatial thinking abilities on higher spatial thinking components, which may be difficult for students with low spatial thinking abilities. Thus, STEM researchers should attend to these low ability components when studying students' spatial thinking abilities, and STEM teachers should take into account students' strengths and weaknesses in spatial thinking when designing and planning relevant lessons, especially when considering complex spatial problems.

Gender gap in spatial thinking

A number of empirical studies indicate that gender differences in spatial thinking ability exist - that male students had better spatial thinking ability than female students. Specifically, some researchers found that male students outperformed females in spatial thinking ability in secondary schools (Li, 2020; Tomaszewski et al., 2015), and others found a gender gap in spatial thinking ability among college students (Shin et al., 2016). The existing gender gap in spatial thinking might influence students' STEM learning, and that female students might lack the spatial skills to succeed in STEM (Li, 2020; Newcombe and Stieff, 2012). Thus, in order to provide students better STEM learning experience, STEM education researchers might investigate ways to narrow the spatial thinking gender gap, and teachers need to consider that some STEM instructional design efforts for imparting spatial ability skills may not be as applicable for female students.

In addition, STEM educators should also consider that a gender difference might exist when conducting an intervention (i.e., STEM activities) in developing students' spatial thinking abilities. For example, using geospatial technologies as a spatial thinking ability intervention, Crews (2008) found that spatial thinking abilities were improved for male students, but not for female students. It might be due to that a gender gap exists in the effectiveness of STEM activities. Thus, if we do not consider spatial thinking ability differences according to gender when conducting STEM activities, differences in spatial thinking ability and gender gap in STEM may be exacerbated. Future research should address gender differences when designing STEM activities centered around spatial thinking abilities.

Facilitating the growth of spatial thinking

Ideally, students' spatial thinking ability should increase along with their age to support their STEM learning, and relevant empirical studies reveal that age was a significant factor in predicting students' spatial thinking abilities (Newcombe and Stieff, 2012; Lee and Bednarz, 2004). For example, university students' spatial thinking abilities are greater than those of secondary school students (Lee and Bednarz, 2004). However, if we take a closer look at secondary school students' spatial thinking ability, researchers found the relationship between grade level and spatial thinking ability was not linear (Li, 2020; Tomaszewski et al., 2015). In other words, students' spatial thinking abilities did not always increase along with their grade levels. This might be a problem in students' STEM learning, since STEM learning in higher grades might require higher order spatial thinking, such as in taking STEM AP classes (Li, 2020).

As stated above, spatial thinking ability is an important and essential ability, not only for students' STEM learning in college level studies, but actually it is more important in students' secondary school study. Thus, we should ask whether middle and high school students are well-prepared for the spatial thinking abilities required for their college studies, and how to best support students' growth of spatial thinking through highly relevant STEM learning.

More importantly, very little attention has been drawn on teachers' growth of spatial thinking ability. In the most recent research, Li (2020) examined middle and high school STEM teachers' level of spatial thinking ability using the STAT. The results of students' and teachers' average percentage of correct answers per question on the STAT can be found in Fig. 2. The results indicate that teachers' and students' patterns of higher and lower spatial thinking ability components were similar. In other words, the ability components that are hard for students are also hard for teachers, such as "comprehending overlay and dissolve," "being able to transform perceptions, representations and images from one dimension to another and the reverse," and "overlaying and dissolving maps" (Gollidge, 2002; Gersmehl, 2005), which are the abilities that demand in STEM teaching and learning. Additionally, in Li's (2020) study, teacher participants were experienced STEM teachers; most had more than ten years of teaching experience. It is important to note that if experienced teachers are not adept at working on spatial problems that require these various ability components, it will be difficult for them to facilitate students' development of spatial thinking ability components. Thus, STEM teachers' spatial thinking abilities growth also need to be paid attention in order to better support the development of students' spatial thinking abilities.

How to cultivate spatial thinking in STEM education?

Although it is tempting to believe that cognitive abilities are fixed, there is copious evidence to support the supposition that spatial thinking ability can be improved through various learning activities (e.g., Terlicki et al., 2008; Wright et al., 2008; Uttal et al., 2013; Gold et al., 2018). Existing evidences in previously studies reveal that there are three effective ways to cultivate students' spatial thinking: (1) Through direct spatial thinking ability training (e.g., Cheng and Mix, 2013; Ehrlich et al., 2006; Wright et al., 2008); (2) Through learning the use of geo-spatial technologies (e.g., Kim and Bednarz, 2013; Milson and Earle, 2008; Madsen and Rump, 2012); (3) Through taking geo-spatial technology integrated disciplinary and interdisciplinary lessons (e.g., Bodzin, 2011; Gold et al., 2018). Newcombe and Stieff (2012) found that the differences among people's spatial thinking abilities may

Fig. 2 Result from Li (2020), students' and teachers' average percentage of correct answers per question on the STAT. Source: Li, S., 2020. Effects of GIS Integration in Secondary School Classrooms: A Mixed-Method Study on Student Spatial Thinking Ability (Doctoral dissertation, State University of New York at Buffalo).

be due to differences in length and frequency of doing spatial thinking related activities, or the use of training techniques that are more efficacious, or both. In other words, it is important to have appropriate techniques, and intervention design, in order to improve spatial thinking ability. Since direct spatial thinking ability training is separate from STEM curriculum, only the use of geo-spatial technologies and taking geo-technology integrated STEM lessons are discussed in this section as effective ways to cultivate students' spatial thinking in STEM learning.

Geo-technology and spatial thinking

Geospatial technologies are technologies for the collecting or processing of data related to space and location; they include geographic information systems (GIS), remotely sensing satellites and aerial images, ArcExplorer, and etc. Those geospatial technologies allow individuals to examine the world through multiple layering of data within a spatial environment (Doering and Veletsianos, 2008). Geospatial technologies have become readily accessible, widely available, and more apparent in our daily lives than ever before (Bodzin and Cirucci, 2009), and they are starting to be used for teaching and learning within STEM classrooms.

Among numerous advanced technologies, Geographic Information System (GIS) is one of the most significant tools to have been called to use in educational reforms and policies. GIS is an integrated system of hardware, software, and procedures designed to support the collection, management, manipulation, analysis, modeling, and display of spatially referenced data about the Earth's surface, in order to solve complex planning and management problems (NRC, 2006). Most importantly, GIS is identified as a potential system for facilitating the development of students' spatial thinking ability (Jo et al., 2016; Lee and Bednarz, 2009; Bodzin, 2011). For the purpose of developing spatial thinking in STEM teaching and learning, NRC (2006) emphasized the significance of using GIS. NRC (2006) stated that "GIS has a clearly demonstrated potential as a support system for spatial thinking" (p. 221) and "must be brought to bear in fostering an understanding for and appreciation of spatial thinking" (p. 241). All students deserve, and need, the opportunity to be challenged, to be supported, and to become critical spatial thinkers, especially in STEM field.

Table 2 shows some sample GIS tools and related spatial thinking components identified by geo-spatial technology experts (Li, 2020). For example, Sketch Up is one of the GIS tools for a wide range of 3D modeling applications such as architectural, interior design, landscape architecture, civil and mechanical engineering. The use of Sketch Up might require the spatial thinking ability component of "being able to transform perceptions, representations and images from one dimension to another and the reverse" (Lee and Bednarz, 2011). Information in Table 2 helps us to figure out that although the GIS tools are not able to cover all the spatial thinking components identified in NRC's (2006) spatial thinking framework, the GIS tools are highly related to several important spatial thinking components. Thus, in order to cultivate students' spatial thinking ability, there is growing interest in studying the use of GIS in STEM disciplinary and interdisciplinary classroom (Bodzin, 2011; Lee and Bednarz, 2009; Li, 2020; Jo et al., 2016).

Table 2 Sample GIS tools and related spatial thinking components (Li, 2020).

Sample GIS tools	Spatial thinking components (Lee and Bednarz, 2011)
Google earth	• Comprehending orientation and direction • Discerning spatial patterns and graphing a spatial transition • Overlaying and dissolving maps • Representations and images from one dimension to another and the reverse • Comprehending integration of geographic features represented as points, networks, and regions • Comprehending spatial shapes and patterns
ArcGIS online and collector	• Discerning spatial patterns and graphing a spatial transition • Overlaying and dissolving maps • Comprehending integration of geographic features represented as points, networks, and regions • Comprehending spatial shapes and patterns
Esri story maps	• Comprehending orientation and direction • Comprehending integration of geographic features represented as points, networks, and regions • Comprehending spatial shapes and patterns
Sketch up	• Being able to transform perceptions, representations and images from one dimension to another and the reverse
Drones	• Recognizing spatial form • Comprehending orientation and direction • Representations and images from one dimension to another and the reverse

Source: Li, S., 2020. Effects of GIS Integration in Secondary School Classrooms: A Mixed-Method Study on Student Spatial Thinking Ability (Doctoral dissertation, State University of New York at Buffalo).

The effectiveness of GIS integration in STEM classes

A number of empirical studies have tested the idea of the NRC (2006) that learning to use GIS can positively impact students' spatial thinking ability (e.g., Lee and Bednarz, 2009; Madsen and Rump, 2012). For example, Lee and Bednarz (2009) studied GIS's effect on university students' spatial thinking ability. They conducted pre- and post-tests with 80 university students before and after taking GIS related courses, such as GIS Introduction and Computer Cartography. Non-GIS users served as the control group in the study. They found that hands-on lab- or project-based experience could improve students' spatial thinking, and greater improvement occurred in skills closely connected to, or supported by, students' experience with spatial representations through their completion of geo-technology course work (Lee and Bednarz, 2009).

Madsen and Rump (2012) also studied the use of GIS as an instrument for developing spatial thinking. The participants for this study were first-year geography major students who took GIS and Cartography courses, and the study focused on students' learning processes in using GIS (Madsen and Rump, 2012). The results of the study indicated that in the process of using GIS, students have different strategies for creating their personal instrument for spatial thinking; it is important to support students in the process of using GIS, to make GIS a personal instrument for the development of their spatial thinking (Madsen and Rump, 2012).

Kim and Bednarz (2013) focused on developing students' critical spatial thinking through the use of GIS. Similarly, they hypothesized that GIS would have a positive effect on students' spatial thinking (Kim and Bednarz, 2013). The participants of their study were upper-level undergraduate students, enrolled in introductory GIS and geography courses. The results indicate that GIS learning is beneficial in enhancing students' critical spatial thinking, identified as the ability to assess data reliability, to use sound spatial reasoning, and to evaluate problem-solving validity.

The above evidences on the effectiveness of using GIS in facilitating students' development of spatial thinking ability are in post-secondary school. Previously research also indicated the use of GIS can also cultivate middle and high school students' spatial thinking (Bodzin, 2011; Li, 2020). For example, Li (2020) examined whether taking GIS integration science, technology, and social study lessons facilitates secondary school students' development of spatial thinking ability. The results indicate that when controlling for students' background, students who used GIS during the academic year had significantly higher spatial thinking abilities than students who did not use GIS (Li, 2020). If we take a closer look at the results, for their control group students who did not use GIS, the difference in their spatial thinking ability between post- and pre-tests was very small. In other words, secondary school students might not improve in their spatial thinking abilities without intervention during the academic year. Thus, the study result not only adds evidence on the effectiveness of GIS use in facilitating students' development of spatial thinking, it also reminds STEM educators that it is important to support students' spatial thinking abilities at the stage of secondary learning, and GIS is a feasible choice when considering early exposure in improving students' spatial thinking abilities.

Approaching "best practice" in facilitating students' spatial thinking

NRC (2006) identifies a great challenge to the development of students' spatial thinking: How might current versions of GIS be incorporated into existing standards-based instruction in all knowledge domains across school curricula? This challenge has not been fully addressed. Most existing studies in GIS intervention were of direct GIS trainings, rather than integrating GIS within

the existing curriculum, which made the use of GIS limited to the subject of geography as opposed to in other STEM disciplines, such as science and technology. Only a few empirical studies support that it is possible to integrate GIS into existing standards-based secondary science, technology, and social studies curriculum, and it was effective in the improvement of students' spatial thinking abilities (Li, 2020). Therefore, when bringing GIS into students' learning, GIS curriculum integration is an effective intervention method that can broaden GIS's applications into wider STEM discipline use, which could better respond to NRC's (2006) call to incorporate GIS in all knowledge domains across the school curriculum. GIS STEM curriculum integration might be the "best practice" in facilitating students' spatial thinking ability.

Ensure enough frequency in taking GIS integrated STEM class

To teach effective GIS integrated STEM lessons which could facilitate students' spatial thinking ability, educators need to ensure sufficient frequency in students' GIS use.

Li (2020) conducted a quasi-experimental study testing the effectiveness of GIS STEM integration in improving students' spatial thinking ability. The results indicate that students who took more lessons with GIS integration tended to have higher gains in spatial thinking abilities, as compared with other students who took fewer lessons with GIS integration. In other words, frequency of taking GIS integration lessons could influence the effectiveness of GIS integration interventions on students' spatial thinking abilities.

For the most part, previous studies found that the outcomes of GIS use in facilitating students' learning were positive. That is, GIS use was positively correlated with gains in students' spatial thinking abilities, or their learning achievement (Bednarz and Lee, 2019; Bodzin, 2011; Kulo and Bodzin, 2013; Gold et al., 2018). For example, Hedley and colleagues (2013) indicated that the use of GIS had a positive effect on students' understanding of atmospheric concept knowledge, and Kulo and Bodzin (2013) reported a significant increase in the energy content knowledge through the use of geospatial technologies. However, other studies indicated an insignificant gain in students' learning outcomes or spatial thinking abilities based on GIS intervention. For example, Crews (2008) indicated that students did not undergo significant changes in their spatial thinking abilities when their teachers participated in geospatial technologies for a professional development project. Li's (2020) findings help with explaining the ineffectiveness of GIS interventions. That is, a longer intervention, with higher frequency of GIS use, may be required to make significant changes in spatial thinking outcomes.

The requirement of a higher frequency of GIS integration intervention lessons may be due to the fact that both students and teachers are inexperienced in using GIS. It could take time for students and teachers to adapt GIS use, especially when integrating GIS in STEM disciplinary teaching and learning. Once students and teachers become familiar and more skilled in GIS use, the experience of taking GIS integrated STEM lessons might then effectively facilitate students' spatial thinking abilities and learning outcomes. Thus, a certain amount of GIS use is important in conducting GIS intervention research, and requires further investigation.

Li (2020) also explored the threshold of GIS integration frequency in STEM class, which might be effective in improving students' spatial thinking abilities. The results present in Fig. 3, which shows students' average gain in spatial thinking ability by different GIS integration frequencies in STEM class. The results indicated that only taking three GIS integration lessons was not enough to make significant change in students' spatial thinking ability; taking 8 to 13 GIS integration STEM lessons per academic year might be necessary. However, the result is still tentative; the exact frequency number deserves future studies. So far, no other studies have investigated the effective frequency and added evidence on this important topic, STEM education researchers are suggested to examine the GIS intervention frequency that could make the most significant change in students' learning and cognitive development (Li, 2020).

Fig. 3 Results from Li (2020), students' average gain in spatial thinking ability by different GIS integration frequencies in STEM class. Source: Li, S., 2021. Effects of GIS Integration in Secondary School Classrooms: A Mixed-Method Study on Student Spatial Thinking Ability (Doctoral dissertation, State University of New York at Buffalo).

Emphasize the role of STEM teacher

To make the use of GIS in STEM classroom more sustainable and realistic in order to facilitate students' development of spatial thinking ability, STEM teachers' role should be clarified and emphasized. In previous studies regarding GIS integration in STEM class, as teachers tend to be familiar with their curriculum but have very limited knowledge and skills of GIS use, STEM teachers' role were weakened in designing the integration lessons. For example, experts in GIS, instructional design and development, science education, environmental education, or educators in other disciplines have usually been involved in designing GIS integration lessons (Bodzin, 2011; Kulo and Bodzin, 2013; Gold et al., 2018); while the majority of teachers spent their time learning how to use specific GIS tools in order to teach lessons to their students. However, this mode of conducting GIS integration lacks sustainability, given that only a single STEM lesson, or set of lessons, within one curriculum topic were designed and taught to students (Bodzin, 2011; Kulo and Bodzin, 2013; Gold et al., 2018); teachers on their own may not be able to further extend the use of GIS in their STEM disciplinary teaching.

Based on the practice and design from prior research regarding GIS curriculum integration in STEM classes and by reviewing the literatures regarding teacher GIS professional development (PD), Li (2020) developed an updated mode of GIS application in STEM class. The mode in Li (2020) allows teacher to have more authority and freedom in designing and teaching GIS integration STEM lessons as compared with that found in previous studies, which made GIS use in the classroom more sustainable.

The study design of Li (2020) is presented in Fig. 4. In particular, a comprehensive GIS training with various GIS tools were conducted with teachers first during 3-week summer camp, which made teachers qualified in using different GIS tools in their classroom. Then, instead of relying on guidance from the researchers, as teachers had the knowledge and skills to use GIS, teachers were the leaders in designing GIS integration classes, with the freedom to choose their GIS tools and STEM class content. In contrast, researchers only facilitated teachers' work throughout the process. Under this design, each teacher designed several different GIS integration lessons, and the lessons covered various STEM disciplines and utilized different GIS tools. With GIS use abilities, teachers can design and teach more GIS integration classes without researchers', or other experts' support. In this way, GIS integration becomes sustainable, more integration lessons can be designed in various disciplines with class content, and more students are able to experience GIS use in their learning. Thus, conducting GIS teacher training first allows teachers to assume a central role in designing and teaching GIS integration lessons that are feasible in GIS interventions in STEM class.

The theory behind the above sustainable GIS STEM curriculum integration mode might also provide insight for STEM researchers in conducting future study. Specifically, Desimone (2009) proposed a core conceptual framework for studying the effects of PD's on teachers and students. This conceptual framework illustrated the path of how effective PD influence students' learning through changing teachers' knowledge, perceptions, and practice, which is presented at the top part of Fig. 5. Guided by Desimone's (2009) model, Li (2020) developed a framework on how GIS integration PD influences students' spatial thinking ability through teacher GIS practice as presented at the bottom part of Fig. 5. It shows how GIS integration PD would increase

Effects of GIS Integration in Secondary School Classrooms: A Mixed-Method Study on Student Spatial Thinking Ability (Doctoral dissertation, State University of New York at Buffalo).

Fig. 5 Pd theory (Desimone, 2009) and the path of effective GIS PD in facilitating student spatial thinking ability (Li, 2020). Source: Li, S., 2023. Effects of GIS Integration in Secondary School Classrooms: A Mixed-Method Study on Student Spatial Thinking Ability (Doctoral dissertation, State University of New York at Buffalo).

teacher knowledge and skills of GIS use, and change their attitude and beliefs toward GIS, which in turn would lead to changes in their instruction, from teaching through traditional methods to teaching GIS integrated STEM lessons. Subsequently, after students taking GIS integrated STEM lessons and experience GIS use in the classroom, their spatial thinking ability could be improved (Li, 2020). Supported by PD theory, the effective paths from conducting STEM teacher GIS PD to the improvement of students' spatial thinking ability were identified in Li (2020). This mode is suggested for STEM researchers to further study in order to continually facilitate students' spatial thinking ability and upgrade the practice of GIS in STEM education.

Summary

Previously literatures have suggested a close relationship between spatial thinking and STEM education (e.g., Uttal and Cohen, 2012; Stieff and Uttal, 2015). Building on prior literatures, the current article elaborates the NRC's (2006) spatial thinking framework and provides several practical suggestions in facilitating students' spatial thinking ability by conducting geo-technology integrated STEM classes. STEM educators and researchers are encouraged to take active steps to ensure that students are well-prepared in their spatial thinking ability - for cultivating future STEM talents and for the improvement of STEM achievement and attainment among all students.

Several highlights of this article are listed below:

- (1) the NRC's (2006) spatial thinking definition reflects a wider variety of academic disciplines, which could be the major framework for relevant researchers;
- (2) Secondary school students' spatial thinking ability are still very low, and may influence students' capacity in STEM learning;
- (3) To have a deep understanding of students' spatial thinking and improve it, researchers need to study spatial thinking by different components and clarify its' relationships;
- (4) STEM teachers' have low spatial thinking ability on some components that are important in their STEM teaching; improving teachers' spatial thinking should also be paid attention to;
- (5) Integrating GIS in students' STEM disciplinary and interdisciplinary learning is evidenced to be an effective and practical way to facilitate students' spatial thinking ability;
- (6) In order to have effective GIS intervention in STEM learning to facilitate students' spatial thinking ability, sufficient frequency in GIS use needs to be ensured;
- (7) STEM teachers should have more autonomy in GIS curriculum integration to make GIS intervention sustainable and practical.

Introduction

As the individual and social importance of computing has grown since the end of the second world war, computer science emerged as an academic field in higher education and more recently in primary and secondary education as well. Modern educational institutions require operational definitions of content knowledge as the basis for curriculum standards, graduation requirements, standardized assessments, teacher certification standards, and other forms of setting goals and measuring progress. Computational thinking has emerged as *boundary object* (Star and Griesemer, 1989) between academic computer science and K12 education, providing a mutually-intelligible construct to practitioners with different needs, different disciplinary practices, and different contexts of use. Computer scientists have tended to approach computational thinking from the inside, introspectively articulating the kind of thinking made possible by thinking-with-computers, which is uniquely characteristic of the field of computer science. Educators and education researchers often approach computational thinking from the outside, asking how these new skills and knowledge should be defined and assessed, and how they might fit into the broader scope of K12 learning goals. The ongoing controversy over how to define computational thinking emerges partly from issues of translation across these contexts and perspectives, but it can also be understood as a proxy for a political debate about the role computers ought to play in society and what children ought to learn in school.

This article provides a history of computational thinking, a summary of computational thinking's role in educational policy and practice, role as a research construct, and concludes by considering the future of computational thinking. Throughout, computational thinking is considered in terms of two opposing questions:

1. How does computational thinking define the heart of computer science?
2. How does computational thinking describe the borderlands?

History of computational thinking

The precursors to computational thinking predate the creation of functional computers. Ada Lovelace, credited with writing the first computer program in 1843, recognized that planning processes of symbolic manipulations (algorithms) represented a form of human thought distinct from the machinery which would carry them out. The machine, she wrote, "can do whatever we know how to order it to perform" (1843, p. 722), and imagined a future in which computers would be able to process symbolic representations of mathematics, language, and music. Although no computer capable of running symbolic programs would be built during her lifetime, Lovelace imagined a future in which new forms of thinking would be brought about by "more intimate practical acquaintance with the powers of the engine" (as cited in Fuegi and Francis (2003), p. 24). Lovelace's famous correspondence with Charles Babbage, who was more concerned with the mechanical details of building a computer, foreshadows the later distinction between computational thinking as a set of abstract knowledge, skills, strategies, and dispositions, and programming as an activity which concretely puts computational thinking to use.

The successful military use of computers in World War II led to speculation about how computers might also transform civilian life. Vannevar Bush, who led the United States's wartime research and development, anticipated that computers would help people find, remember, and organize the exponentially-growing amounts of information generated by society (1945). Perlis argued in the early 1960s that programming ought to be a standard part of a liberal education, enabling everyone to frame problems in computational terms (Guzdial, 2008). Engelbart's (1962) goal of using computers to augment human intellect led to the invention of personal computing and ultimately today's consumer computer ecosystem. As computers became smaller and less expensive,

educator-technologists such as Papert (1980) and Turkle (1984) explored how computers might offer powerful learning experiences to children.

Papert, the first to use the phrase “computational thinking” (1980, p. 182), was interested in using computers not “to put children through their paces” (1980, p. 19) but to serve as partners in thought providing contexts and representations through which children might form personal relationships with powerful ideas. He was dismayed at the tendency of school curricula to focus on the delivery of denatured and decontextualized “content,” similar to Freire’s (1968) critique of the “banking concept of education.” Writing about probability, for example, Papert argued that “one of the most powerful ideas in our intellectual heritage is (not untypically) disempowered in its school presentation, where it is reduced to shallow manipulations that seldom connect to anything the student experiences as important” (1996, p. 4). Papert argued that computers could serve as “micro-worlds” in which children might learn powerful ideas as easily and naturally as children learn French by growing up in France. Building off the work of Piaget and Vygotsky, Papert and later Constructionists hypothesized that computer cultures might produce new developmental trajectories for children and new futures for society.

The current era of computational thinking begins in 2006, when Wing’s argument for computational thinking as a “universally applicable attitude and skill set everyone, not just computer scientists, would be eager to learn and use” (p. 33) catalyzed legislatures, policymakers, researchers, and businesses around the goal of *CS for All*, or adding computer science to the fundamental competencies every child should develop throughout primary and secondary education. Wing defines computational thinking as involving “solving problems, designing systems, and understanding human behavior, by drawing on the concepts fundamental to computer science” (p. 33). The article offers a long list of examples of computational thinking, starting with concepts such as recursion, parallel processing, type checking, and indirect addressing, which have specific technical meanings in computer science but which could be applied more generally if one frames a problem in computational terms. She encourages such abstraction, providing several examples of how concepts from computer science can be used to reinterpret situations from everyday life and envisioning a future in which computational ways of thinking about the world have become widespread and privileged: “Computational thinking will have become ingrained in everyone’s lives ... when trees are drawn upside down,” suggesting that tree-as-data-structure will have eclipsed the ecological concept of a tree (p. 34).

Wing offers a number of criteria for locating the boundaries of computational thinking which have been broadly influential in shaping the development of the concept in policy and research, as well as presciently indexing some of its key definitional tensions. First, she argues that computational thinking is “conceptualizing, not programming” (p. 35), an idea later interpreted by numerous standards documents to mean that computational thinking and programming are disjoint—a starker distinction than Wing may have intended. Furthermore, computational thinking is “fundamental, not a rote skill” (p. 35), anticipating the argument that computational thinking ought to be the emphasis in general and interdisciplinary education, leaving programming to the subset of students preparing for specialized careers in computer science and engineering. Wing suggests that computational thinking “complements and combines mathematical and engineering thinking” (p. 35), an assertion explored in subsequent literature on what is distinct about computational thinking and how it relates to other forms of disciplinary thinking. Finally, Wing argues that computational thinking is about “ideas, not artifacts” (p. 35), echoing prior arguments (e.g., Dijkstra, 1989) that computer programs ought to be taught as formal mathematical systems and not in terms of their behaviors.

Wing’s definition of computational thinking would form the basis of a rapid adoption of computational thinking as a primary and secondary learning goal around the world. As the concept was put into practice in educational policy and research, tensions and contradictions emerged around how computational thinking should be defined and how it should be taught. Computational thinking found its way into schools through standalone computer science courses as well as through interdisciplinary implementations across the curriculum, leaving researchers to reconcile narrow and broad conceptualizations.

Computational thinking in educational policy and practice

The goal of universal K12 computer science education was taken up by a coalition of public- and private-sector advocates of computing education such as the Association for Computing Machinery, Code.org, the Computer Science Teachers association (computer scienceTA), the International Society for Technology in Education (ISTE), the UK’s Computing at School, and the Australian Curriculum, Assessment, and Reporting Authority. These groups pursued a strategy of uniting behind a clear, uniform definition of the essential skills and knowledge of computer science, and they selected computational thinking as this definition despite unresolved details about the meaning and scope of the term, noted above (Barr and Stephenson, 2011). Computer science was introduced as a standalone course (particularly at the high school level) as well as an interdisciplinary literacy which could be taught across the curriculum; as a result, computational thinking was tasked with articulating both the essential heart of computer science as well as its interdisciplinary potential.

Major reports commissioned in the United States (Wilson et al., 2010) and the United Kingdom (The Royal Society, 2012) found that schools were far from preparing students with the computing skills they would need in the anticipated digital economy, and called on governments to create K12 computer science standards organized around computational thinking. Following initial standards developed by computer scienceTA (2011) and ISTE (2011) identifying computational thinking as a core strand of computer science, a broad coalition of stakeholders developed the K12 Computer Science Framework (2016) to guide individual states in defining their computer science content standards. This framework proposed seven core practices at the heart of computer science, and identified four of them as comprising computational thinking: recognizing and defining computational problems; developing

and using abstractions; creating computational artifacts; and testing and refining computational artifacts (p. 68). The framework largely followed Wing's earlier definition of computational thinking, emphasizing that computational thinking is distinct from computer science, that computer science is the best context for learning computational thinking, and that computational thinking should be included in standards for other subjects as well.

These efforts to define computational thinking laid the groundwork for computational thinking educational policy initiatives around the world. A 2019 review of global computational thinking educational policy initiatives (Hsu et al., 2019) found that five countries had implemented national computational thinking curricula: the United Kingdom, Australia, the United Arab Emirates, Finland, and Russia. Others, including India, Chile, Japan, China, Korea, Taiwan, and Hong Kong, have processes underway (Hsu et al., 2019; So et al., 2020). Hsu et al. (2019) found wide conceptual variety in how computational thinking is defined, as well as how computational thinking is understood to relate to computer science and to programming. National curricular reforms vary in the extent to which they implement computational thinking by adding computer science as a new subject area or embed interdisciplinary computational thinking across existing subject areas.

In addition to interdisciplinary applications, computational thinking has been used as a bridge between formal academic computer science and other contexts. Although many authors caution that the mere use of a computer (in or out of school) does not imply the presence of computational thinking, informal contexts such as clubs and online communities have been particularly important places for learners who have been marginalized by formal computer science to develop interest and experience which may serve as the foundations of computational thinking learning (National Academies of Sciences, Engineering, and Medicine, 2021). Informal learning environments have also been particularly welcoming to sociocultural reframings of computational thinking (Kafai and Burke, 2013; Reppenning et al., 2010), discussed in more detail below.

A lack of access to early computing experiences also plays a role in inequitable computer science participation (Margolis and Fisher, 2003), leading to increased emphasis on computational thinking learning opportunities earlier in high school (e.g., introductory courses such as Exploring Computer Science (Goode and Margolis, 2011)), the middle and primary grades, and even early childhood education. Wang and Proctor's (in press) review of computational thinking in early childhood education finds significant tensions between standard framings of computational thinking which prioritize interpreting phenomena in terms of computational models and the holistic developmental priorities of early childhood education. Instead, approaches grounded in Papert's understanding of computational thinking as a relationship between learners and computers has found more traction (Bers, 2017).

Assessment of computational thinking

Implementation of computational thinking standards and curricula is still quite recent so standardized assessments of computational thinking are generally not yet in place. As of 2010, "assessments for computer science education [were] virtually non-existent" (Wilson et al., 2010, p. 14). Assessment tends to drive implementation in K12 education (Eisenhart et al., 1996; Grover and Pea, 2013), so it is not surprising that the development of computational thinking assessments has been a policy priority as well as an active area of research. The development of assessments has also helped surface tensions within definitions of computational thinking, as an assessment requires precisely operationalizing a construct and resolving ambiguities in standards.

Brennan and Resnick's (2012) exploration of how computational thinking might be assessed remains by far the most cited framework for approaching the assessment of computational thinking. Brennan and Resnick identify three dimensions of computational thinking—concepts, practices, and perspectives—and consider several process-based strategies for assessing them, including studying students' design processes, artifact-based interviews, and design scenario tasks. Brennan and Resnick's focus on the process of artifact creation rather than the product is motivated by their primary interest in supporting youth in creating personally-meaningful artifacts, but their argument aligns with other arguments for attention to process. An artifact created with code does not constitute evidence of computational thinking without also considering the process with which it was made ("K-12 Computer Science Framework," 2016; Salac and Franklin, 2020). Similarly, Denning (2017) argues for understanding computational thinking as a competency characterized by how people think about problems (specifically, employing abstractions which represent a problem in terms of a computational model), not just what they know or what they have produced. This view presents a challenge to the decontextualized, content-based standardized testing characteristic of national policy initiatives.

Another difficulty in assessing computational thinking is that computational thinking appears to be tightly-bound to the modality in which computational thinking has been learned (Weintrop and Wilensky, 2015), reinforcing the importance of the relationship between cognition and the medium of representation (Wilensky, 2010). Despite the argument for the broad applicability of computational thinking, students' skills do not transfer easily between programming languages or representations, nor is there evidence that computational thinking improves intelligence in general (Guzdial, 2015; Pea and Kurland, 1984). To address this dependence on modality, Werner et al. (2012) developed a performance assessment embedded in the programming environment and task structure students had been using to learn computational thinking.

Several recent reviews conclude that substantial difficulties remain in the assessment of computational thinking. In terms of Brennan and Resnick's framework of concepts, practices, and perspectives, the vast majority of computational thinking assessments around the world focus on concepts, with little consensus on which concepts are included and how they are defined (Cutumisu et al., 2019). Most assessments are designed to test content knowledge without attending to process, and very few have been validated (Lye and Koh, 2014; McGill et al., 2019). Computational thinking assessment has made substantial recent progress in early childhood education, with efforts to stabilize the construct (Bers, 2017) and a validated assessment (Relkin et al., 2020).

Computational thinking as a research construct

As suggested by the uneven state of computational thinking assessment, the uptake of computational thinking in educational policy has outpaced its development as a research construct (Wilson and Guzdial, 2010). Since Wing's 2006 article, researchers have engaged in a spirited debate about what computational thinking ought to mean and how it ought to be defined, measured, and taught. However, based on the distribution of citations, this debate has had more urgency within the computer science education community than in the broader literature on education (Saqr et al., 2021). Empirical research on computational thinking often begins by recounting the history of these disagreements before proceeding with an ad-hoc measure of computational thinking. The two questions organizing this article, *How does computational thinking define the knowledge, skills, and practices at the heart of computer science?* And *How does computational thinking describe the borderlands?*, represent proximal and distal poles in a fundamental question underlying much of the controversy around computational thinking: how broad is computational thinking? (Proctor and Blikstein, 2018; Voogt et al., 2015).

How does computational thinking define the heart of computer science?

Between roughly 2006–2013, the academic conversation around computational thinking focused largely on how the construct articulated the heart of computer science, itself a dynamic and loosely-bounded discipline. In 2009 the US National Research Council convened a workshop aimed at defining the scope and nature of computational thinking. While the participants did not reach consensus on either topic, they did largely agree on the centrality of computational thinking in computer science, and that computational thinking is fundamentally a process of abstraction. In a subsequent article, Wing (2011) developed this idea into a concise definition of computational thinking:

Computational thinking is the thought processes involved in formulating problems and their solutions so that the solutions are represented in a form that can effectively be carried out by an information-processing agent (p. 1).

The workshop also considered the relationship between computational thinking and programming. Although examples of unplugged pedagogies (by which computational thinking is taught without the use of computers (Bell et al., 2009)) were shared, the workshop appeared to generally agree that while computational thinking is distinct from programming, code plays an important role in computational thinking. This is embedded in Wing (2011) definition, as programming is a primary (though not the only) mode of representing solutions which can be interpreted by a computer. In the words of Mitchel Resnick, “computational thinking is more than programming, but only in the same way that language literacy is more than writing ... programming, like writing, is a means of expression and an entry point for developing new ways of thinking” (p. 13).

These two findings—that computational thinking describes a thought process of applying abstractions to problems, and that programming plays an important role in computational thinking—are notable in retrospect for the extent to which they have been minimized in the implementation of computational thinking in policy and practice. In the decade following Wing's 2006 article, numerous frameworks proposed taxonomies of what should be included within computational thinking, with substantial variation (Angeli et al., 2016; Barr and Stephenson, 2011; Brennan and Resnick, 2012; Grover and Pea, 2013; Kalelioglu et al., 2016; Repenning et al., 2016; Seiter and Foreman, 2013; Selby, 2012). Abstraction (the “undisputed” keystone of computational thinking (Grover and Pea, 2013, p. 39)) was always included as a core element of computational thinking; algorithms, data, decomposition, parallelization, testing and debugging, and control structures were often included as well (Zhang and Nouri, 2019). A recent review proposed six facets of computational thinking: decomposition, abstraction, algorithm design, debugging, iteration, and generalization (Shute et al., 2017). Nevertheless, K12 computational thinking curricula and assessments disproportionately address computational thinking concepts, suggesting that computational thinking is taught as a body of knowledge rather than a process (Lye and Koh, 2014).

Recent implementations of computational thinking have also de-emphasized programming for principled and for practical reasons. In contrast to Resnick's quotation above suggesting programming is like writing, Lu and Fletcher (2009) view programming as a specialized practice, unnecessary and uninviting for beginners: “programming is to Computer Science what proof construction is to mathematics, and what literary analysis is to English” (p. 260). Others have suggested that teaching programming focuses students' attention on low-level details which are becoming less important as interaction with computers progresses to higher-level abstractions (Pears et al., 2021). In primary and secondary education, teaching computational thinking without programming has had an easier time finding purchase in interdisciplinary contexts and as the basis for pedagogical approaches which are manageable for teachers without a background in computer science.

As computational thinking gained widespread adoption in K12 education globally, concerns emerged from within the academic computer science community that the desire for broad applicability had led to an overly-vague definition of computational thinking which had lost its focus on the essential process of framing problems in computational terms (Tedre and Denning, 2022). Denning (2017) envisions computational thinking defined in terms of competencies—skills and sensibilities demonstrated in practice—while noting that assessments of computational thinking are largely focused on static content knowledge. He takes issue with curricula based on these assessments structured as “progressions of increasingly sophisticated learning objectives” rather than sequences

of skill acquisition (p. 36). Even if programming is not necessary in computational thinking, Aho (2012) emphasizes the centrality of computational models (formal systems which can run automatically) in computational thinking, arguing that interdisciplinary computational thinking requires a discipline's constructs discipline to be represented in terms of a computational model. Computational models are widely-accepted in adjacent STEM fields such as the life sciences, but in the social sciences and particularly the humanities, whose questions more often address interpretation, positionality, and subjectivity, the role of computational models is less clear.

Grover and Pea's (2013) review of computational thinking in *Educational Researcher* marks a milestone in the research trajectory of computational thinking, taking stock of progress and projecting the research agenda ahead, while also mediating the perspectives of the computer science education community and the broader community of educational research. After summarizing the prior research on computational thinking (much of which, they note, was focused on defining computational thinking), Grover and Pea proposed broadening the scope of computational thinking research by focusing on interest, identity, and stereotypes contributing to a lack of diversity in computational thinking enrollment, computational thinking research grounded in sociocultural and situated theories of learning, and interdisciplinary computational thinking. At the same time, they called for more empirical research on K12 computational thinking practice, including the development of evidence-based curricula, pedagogies, and tools for K12 computer science and models for integrating computational thinking into professional development and teacher preparation. While Grover and Pea's review does not demarcate a clean division, it marked a shift in emphasis from computational thinking as it relates to computer science to computational thinking as it relates to K12 education more broadly.

How does computational thinking describe the borderlands?

The term *borderlands*, referencing Anzaldúa (1987), points to liminal spaces and the possibilities of hybridity, crossing, or syncretism drawing on multiple sources. The borderlands of computational thinking are at the edge of what counts from the perspective of computer science, sometimes crossing into other disciplines or communities of practice with their own perspectives and priorities. The borderlands include teachers and students in schools and informal contexts (who may be more interested in creating meaningful experiences than fidelity of implementation), those oppressed by race, gender, or other categories (who may be indifferent or hostile to their powerful computing practices being identified as computational thinking), computational thinking in interdisciplinary contexts (where computational thinking may play an instrumental role in the service). As computational thinking has made its way into K12 practice over the last decade, the community of researchers interested in computational thinking has expanded to include those whose primary concern is these spaces and peoples.

Following the 2009 National Research Council workshop on the scope and nature of computational thinking, another workshop was convened to consider the pedagogical aspects of computational thinking (National Research Council, 2011). Although K12 teachers were not represented, the workshop affirmed the importance of teachers and pedagogical skill, and recognized the potential for computational thinking in formal primary and secondary education, as well as informal spaces. As the visibility of computer science practitioners grew within the computing education research world (led by the Computer Science Teachers Association), an alternative emerged to the theoretical debate over how to define computational thinking. The Use-Modify-Create framework (Lee et al., 2011), in which a group of researchers based in K12 schools and informal contexts chose to focus not on what computational thinking means in theory, but what it looks like in practice. The report aimed to help educators understand and teach computational thinking in the context of children's socioeconomic and cultural contexts and their developmental trajectories. In the framework, students first *use* computational artifacts created by others in order to understand their external functionality, then *modify* artifacts to understand their inner workings, and finally *create* their own artifacts. This strategy grounds computational thinking in a sociocultural account of learning, aiming to support students' inbound trajectories of participation and developing a sense of authorship and agency with the artifacts and the code in which they are implemented. The epistemic importance of teachers has only grown, with recent calls to substitute the top-down, "abstract and agenda-driven" processes for defining computational thinking and designing pedagogical approach with emergent definitions grounded in local needs and realities (Wilkerson et al., 2020, p. 265).

A substantial body of literature has documented the persistent inequities present in K12 computer science education. Equity-oriented researchers studying how mainstream computer science learning environments tend to support dominant-culture youth at the expense of their marginalized peers have found it useful to frame learning in terms of sociocultural constructs such as identity-building (Shaw and Kafai, 2020; Vakil, 2020) and participation in communities of practice (Scott and White, 2013), and to examine the relationship between computing and structures such as race and gender (Benjamin, 2019; Margolis and Fisher, 2003). However, these sociocultural and critical perspectives are substantially less present in the literature on computational thinking. The K12 Computer Science Framework (2016) recognizes the importance of practices such as collaboration, communicating, and fostering an inclusive computing culture, but clearly demarcates them from computational thinking. Similarly, the AP Computer Science Principles course, which was designed around computational thinking, views creativity and collaboration as "pedagogical strategies to be used to develop a diverse, appealing, and inclusive classroom environment" rather than as part of computational thinking (College Board, 2020). In empirical research, race, gender, and other categories are more often treated as contextual factors or moderating variables, rather than as formations shaping the nature of activity.

If computational thinking is essentially about the process of formulating problems so that their solutions can be carried out by an information-processing agent, sociocultural and critical constructs are relevant to who is formulating which problems, and to what end. Vakil's (2018) agenda for a justice-centered approach to equity in computer science education would emphasize the

social and political implications of computational thinking, and the disciplinary, civic, and political identities which authorize students and legitimize problems as suitable for computational thinking. Similarly, ethnocomputing applies the processes of computational thinking to the “knowledges, practices, and designs of Indigenous or vernacular cultural systems” (Lachney et al., 2022, p. 112). Several alternatives to computational thinking have also been proposed, such as *computational participation* (Kafai and Burke, 2013) *computational action* (Tissenbaum et al., 2019), and *computational literacies* (Kafai and Proctor, 2021) which view constructs such as identity, interest, power, and formations (Omi and Winant, 2001) such as race and gender as integral to the practices of computational thinking.

Finally, interdisciplinary borderlands of computational thinking have been receiving increasing attention at the K12 level, following the increasing importance of computing in research across disciplines (National Research Council, 2010). Computational thinking has been deployed in an effort to “highlight the integral relationship between computing and other fields” (Wilkerson et al., 2020, p. 264). K12 STEM disciplines have eagerly adopted computational thinking. For example, the Next Generation Science Standards include computational thinking among the core practices of science (Weintrop et al., 2016). Domain-specific “teaspoon languages” have recently been developed which “add a teaspoon of computing to other subjects.” The goal is that by the time that US students take a computer science class (typically, in high school or undergraduate), they will have had many programming experiences, have seen a variety of types of programming languages, and have a sense that “programming isn’t hard” (Guzdial and Shreiner, 2022).

Three framings of computational thinking

The two questions organizing this article are positioned respectively within computer science and within K12 education. They represent different stakeholders in the research community, and are oriented toward different future research trajectories, raising the prospect of fragmentation of the computing education research community. In response to a proposal that computing education ought to avoid *theory bias* by limiting its engagement with educational theory (Nelson and Ko, 2018), Kafai et al. (2020) argued that all accounts of learning are grounded in theoretical frames and instead proposed a commitment to *theory dialog*. Their goal was to avoid the so-called “literacy wars” and “math wars” in which researchers committed to different paradigms were unable to find common ground with respect to disciplinary learning goals, what would constitute evidence of success, or sometimes even legitimate methods of research.

Toward this end, Kafai, Proctor, and Lui identified three framings of computational thinking: cognitive, situated, and critical, which distinguish the theoretical underpinnings of various projects within the computer science education research community. Cognitive computational thinking seeks to provide students with an understanding of key computational concepts and competencies. Situated computational thinking understands learning in terms of creative expression, interest development, and identity authorship and participation. Critical computational thinking recognizes that computing is not an unequivocal social good, and proposes an analytical approach to the values, practices, and infrastructure underlying computation as part of a broader goal of education for justice and participation in shaping our shared future.

Kafai, Proctor, and Lui represented these framings as three concentric circles, suggesting units of analysis at the scale of the individual, the collaborative group, and the city or society. These three framings are loosely parallel to the concepts, practices, and perspectives proposed by Brennan and Resnick (2012). Just as the vast majority of computational thinking assessments currently focus exclusively on concepts, cognitive framings of computational thinking remain dominant. As the social importance of computing continues to grow and educational stakeholders from outside of computing education participate in the academic conversation around computational thinking, the authors hope that situated and critical research will be legible to researchers whose work is largely cognitive and dialog across framings will be possible.

The first decades of the 21st century have seen widespread adoption of computational thinking as an educational priority around the world, accompanied by a research base whose growth continues to accelerate (Saqr et al., 2021). As the social importance of computing continues to grow, computational thinking appears to be well on its way toward becoming a fundamental literacy at the heart of K12 education. With this integration the two questions anchoring this article, asking how computational thinking defines the heart of computer science and how computational thinking describes the borderlands, are likely to be increasingly in dialog with each other.

Introduction

Science, Technology, Engineering and Mathematics (STEM) education has been identified by the Australian Government as being of critical importance to the economic future and development of Australia (Department of Education, Skills and Employment, 2019). This in turn has led to a STEM policy focus that prioritizes STEM for future careers which, as Panizzon et al. (2018) forewarn, could promote a narrow interpretation of STEM. However, the Australian Government’s focus on careers related to STEM has led to an increased emphasis on STEM in primary and secondary schools. The implementation of STEM in schools has taken many forms and the extent of its success has varied. While there are many positive examples of STEM practices in schools, there are also elements such as inflexible timetable structures, particularly in Secondary Schools, that can be a barrier to its implementation. This article is based on our work with teachers and students across a range of STEM in Schools projects. For example, O’Keeffe et al. (2018, 2021), Panizzon et al. (2021), Scott et al. (2021).

To support teachers in planning specific conceptual and skill development through STEM inquiry, there needs to be a focus on planning for intentional learning. While students are often able to articulate *what* they have produced as part of an inquiry project they do not always recognize, and are not always able to articulate, the scientific/mathematical/technological concepts involved. Besides reframing their practices in planning for inquiry-based learning, the formulation of sound questions, be they the teachers or their students, is critical to the success of an inquiry. Moreover, some teachers have found it difficult to make links to the mathematics curriculum and have felt that what had been delivered was “tokenistic” and lacked the conceptual depth for student learning in this area. In this article we discuss the importance of inquiry based, question oriented pedagogical approaches as well as why mathematics is essential in STEM focused inquiry-based learning.

Inquiry-based learning is closely connected with STEM teaching learning and many descriptions of STEM education include inquiry in some form. For example, the “Guiding principles for schools to support STEM education” in the Australian “National STEM school education strategy 2016–2026” which has as one of its principles

Build on students’ curiosity and connect STEM learning to solving real world problems, including through collaborative and individual learning experiences that are hands-on and inquiry-based and support the achievement of deep knowledge.

Education Council (2015, p. 11).

While Inquiry-based learning is not restricted to STEM alone, researchers such as Bybee (2013), have included inquiry as an aspect of STEM literacy while Kennedy and Odell (2014) identified inquiry as a component of high-quality STEM programs. Inquiry can also be viewed as an approach to teaching (Metz, 1995) which allow students to “engage in authentic and meaningful activities that are connected to the real world” (p. 538). For example, Paige et al. (2020) discuss the ways in which inquiry-based approaches to STEM can connect students/young children to their local areas by authentically engaging them in local issues via an eco-justice or sustainability lens. As Scott et al. (2021) found,

Inquiry-based learning (IBL) approaches have the capacity to transform practice from a passive transmission type teaching approach to something more engaging, cognitively stimulating, and ultimately more effective for learning.

Teaching Science (2021).

The extent to which STEM based inquiry projects align to what might be considered the traditional school curriculum can sometimes be unclear to teachers. Addressing this requires strategies such as mapping the project against each of the STEM components. This planning process incorporates the conceptual requirements, pedagogical approach, and assessment of learning. Assessing student learning can be problematic in STEM inquiries because the range of curriculum requirements, the

additional skills required for inquiry, and the diversity of ways for students to communicate project outcomes are not always part of a system's customary assessment and reporting process. Thus, teachers need to understand that while learning design principles for STEM inquiries may be qualitatively and mechanistically different from learning through other pedagogical strategies, they can assist their planning for learning. Such an approach has the potential for some teachers to minimize planning for full engagement in a STEM inquiry project, and could initially result in a project being "trialled" as an addition to the regular curriculum requirements.

The structure and content of inquiry-based projects are by their nature diverse; however, some common features can be found. For example, from our experiences in working on several STEM focused professional learning projects with schools in both metropolitan and regional areas, and from private and public systems, inquiry-based projects had either a question or a problem to be "solved" by groups of students. In reporting their experiences of using this approach to address STEM, teachers said that it had increased the collaborative opportunities for students to work together and had developed skills such as clear communication. The projects also fostered skills relevant to STEM, such as critical thinking, collecting data, using information to generate ideas, and being able to gather additional information to expand their ideas.

When implementing the STEM inquiry projects in schools, we found that teachers needed time to develop the classroom practices and processes required. Initially teachers worked through an "exploration" phase where they trialled their approach. In this initial stage the STEM inquiry projects often missed key elements in planning such as deep conceptual connections for each curriculum area, or clear assessment tasks. However, this form of productive struggle, or of being in the "Learning Pit" (Nottingham, 2016, p. 109), was deemed a critical component in teacher change. This struggle became even more evident in situations where new teachers joined a project in its second year (due to teacher turnover after the first year). While these teachers had the advantage of learning from their colleagues already in the project, in most cases they found the approaches now being implemented by their colleagues too daunting, for example in managing student agency. Instead, they opted to work through the initial "exploration" phase with its narrower, more focused approach. With time and practice, these teachers then worked through the second phase and "refined" their approach, ensuring a greater focus on student inquiry, clear curriculum connections and focused assessment (Scott et al., 2021). These teachers also spoke of "next year" demonstrating that they had already reflected on aspects of their approach that could be improved to enhance student learning. Interviews with the teachers, particularly those who worked on collaborative projects for two or more years, reported significant increases in their confidence to organize inquiry-based learning in their classrooms, about their knowledge of enacting an inquiry-based learning approach and, about how this might be more fully implemented in their classrooms.

The teachers with whom we worked across a range of different teacher professional learning projects often wanted to be able to extend opportunities for their students to experience authentic STEM-related activities. This goal motivated them to actively engage their students with local industries and community-based projects, enabling students to realize the application of STEM outside of the school environment. Connection to community was established in a variety of ways, for example, with the local council or with a local industry. Overall, the breadth and depth of inquiry-based projects in which teachers engaged their students ranged from projects that teachers developed using structured inquiries, to those that were wholly student designed and implemented. We found that the more student agency allowed for within an inquiry-based project the more students were able to provide detailed articulations of their learning across different disciplines and/or skill capabilities.

Across the STEM projects we consistently found that, where teachers had autonomy, strong leadership support, an opportunity for collaboration with their colleagues, and access to external professional development, or industry connections, then authentic, student led inquiry was well integrated into their teaching. This in turn has the potential for a positive impact on their general pedagogical practices, as well as on student dispositions and attitudes toward the individual STEM disciplines.

Inquiry-focused questioning for STEM

As Oliveira has reported (2010, p. 422), there is growing evidence in the science education literature that teachers commonly have difficulties interacting with students in inquiry-based settings. In our work with teachers within and across schools, when investigating what changes in curriculum, pedagogies and/or practices were evident from teachers' involvement in inquiry-based STEM projects, we found that three elements stood out as being particularly influential to teachers:

- The ongoing support at multiple levels (School, Sector, University) through professional learning workshops, and the affordance of the project to take a chance and try something new or something the teachers have wanted to try out,
- The opportunity for these teachers to plan and implement STEM curriculum as a group of teachers (within school or across school collaboration), and
- The ongoing refinement of the teachers' understanding of STEM and its connection to the Australian Curriculum.

A focus of the STEM-based projects that we developed was on pedagogical change through an inquiry-based teaching approach. This generally involved professional learning through a series of workshops with all the teachers. The workshops were designed to build teacher confidence and expertise in the planning, assessment, and teaching of STEM discipline knowledge and skills through experiencing this themselves. The workshops were also typically supported by small group sharing and mentoring of the teachers during half day, school-based meetings.

Teacher and student engagement with STEM can be fostered through an inquiry-based approach that also involves reasoning and critical and creative thinking through the generation and utilization of questions that connect student interest to meaningful learning. Fundamental to this is the need for teachers to pose intellectually challenging questions that foster a curiosity for intentional learning. As Toshalis and Nakkula (2012, p. 2) commented, “research has shown that the more educators give their students’ choice, control, challenge, and opportunities for collaboration, the more their motivation and engagement are likely to rise.” To be able to do this well, teachers themselves need both the confidence and preparedness to pose questions that they themselves might not know to answers to. They need to take the time to explore and extend their own questioning skills to first foster student interest in STEM based inquiries and second, to encourage their students to ask intellectually significant questions that lead to inquiry-based STEM investigations. As Sedova et al. (2016, p. 15) found, “It makes sense to teach teachers the specific skills of dialogic teaching.” Hence, in our work with teachers we typically included a focus on teachers practicing, developing, and extending their STEM focused questioning skills. For example, in one project we challenged participants to identify key differences between utilizing open and closed questions while fostering inquiry-based student learning. This was enacted through introducing an unusual object to them (e.g., an early 1900s coal fueled iron) and posing questions that ranged from “what is this object used for/made of” to “what else could it be made of/used for/improved by?” In small groups the participants then examined a range of arthropods and either asked or answered closed questions to be able to identify them in a “line-up.” This was intended to foster animated discussion about the questioning process (closed vs. open), the difficulty in asking students focused yet inquiry generating questions and, the necessity for clarity of language when questioning with purpose. A final phase was to develop and apply questioning skills. Our example used pictures of shoes through the ages, where participants were tasked with generating open questions and interrogating the STEM related connections that included mathematical, scientific, and technological elements. For example, “How might the construction of a heel influence it’s balance?” As Zeegers and Elliott (2018, p. 3) found, “Implicit in these approaches is the need for teachers to pose intellectually challenging and engaging questions in the classroom.”

In the following section, a case study of two teachers from one of the project’s primary schools has built on the previous provocations around questioning to utilize inquiry-based questioning as the launch pad for engaging students in a STEM related learning theme lasting one school term.

This school in which this case study is located is a small (~350 students) co-education Catholic school located in the metropolitan areas of Adelaide, South Australia. Teachers, Cara, and Mary (pseudonyms used) had opted to take part in our 2-year STEM inquiry project that was centered on developing STEM inquiry-based projects that were either within, or across school collaborations.

Cara and Mary’s aim for the 2-year project was to “develop a school-based STEM philosophy to inform the teaching and learning practices at their School using a focus on the design of a new learning space linked to the School’s Building Project.” In 2018 the Year 4/5 students had explored the features of classroom design that would make comfortable and environmentally friendly learning spaces. The emphasis was on designs for breakout spaces inside the building.

In 2019, Cara and Mary’s first steps were to identify an authentic inquiry for the junior primary aged students. As such, their project remained focused on the funded 2-year school building project that included a dedicated STEM room with 2 breakout spaces and extended this to having students design some outdoor learning areas. While the inquiry’s focus was on STEM and how teachers could incorporate student input to help design and create engaging learning spaces within the build, the project also provided multiple opportunities for addressing Australian Curriculum General Capabilities including Literacy; Numeracy; Information and Communication Technology Capability, Critical and Creative Thinking and, Personal and Social Capability.

The teachers involved their forty-four 6-year-old students acting as sound engineers to explore elements that could be included to create an engaging outdoor area for other students. The students’ task was to design and create a model of a sound-making element that could be added to the outdoor space. To build on student curiosity, the teachers discussed the processes used by engineers and designers to solve a problem by creating new products, systems, or environments. The TASC (Thinking Actively in a Social Context) Framework (Wallace, 2019), was used to record student ideas throughout the process. This visual reminder was on constant display in the classroom and enabled students to refer to these ideas when creating their designs. Cara and Mary also used this framework to plan out learning experiences that included gathering students’ prior knowledge and questions about sound, to having them then design, create and test a sound-making element prototype. As part of their teaching approach Cara and Mary sent a note home asking for recycled materials so that students could create their own instruments and explore how sounds were made. They encouraged students to go outside and investigate elements of sound. They also set a “School Holiday Playground Challenge” wherein students returned to school with photos of places they had visited and things they had discovered about sound. Students then participated in an African drumming incursion where they explored beat and rhythm and discovered the materials used to make traditional instruments. The students also visited a local park to investigate and experience sound elements during play.

Part of their planning included some Explicit Direct Instruction because Cara and Mary wanted to ensure the students had an accurate knowledge base, they could use prior to creating their prototype. With a focus on “*the Science in Sound*,” students investigated how they could make sound by singing a nursery rhyme with their hand over their throat and explaining what they noticed; completed a pitch and volume investigation; discovered how they could make an instrument play a soft sound or a loud sound; listened to sound effects and discussed how the sound is made and heard.

In tune with the STEM focus, in *Mathematics* the emphasis was on measurement, with students investigating how length and volume affect the pitch; looking at the length of the bars on a xylophone; creating musical water jars and comparing the sizes of

a range of instruments; In *Technologies & Arts* the students investigated making sound, identifying how sound can be manipulated (changing the pitch) and, investigating which materials were suited to making instruments. Recycled materials were used to make a range of different musical instruments including drums and maracas. The unit connected with National Simultaneous Story-time which featured the book “Alpacas with Maracas.” In their specialist music lessons, students explored beat and rhythm using songs including the Queen song “We Will Rock You.” In *English, Humanities, and Health*, students were introduced to exposition focused writing by exploring language that could be used to present a point of view. They investigated distinctive features of places such as play spaces, comparing their experiences to the experiences of their parents or grandparents. They also explored the features of traditional indigenous instruments including rain sticks, clap sticks and the didgeridoo. In addition, because two students had cochlear implants, Nicola from “Can: Do 4 Kids” talked to all the students about how their ears function and how cochlear implants work.

Equipped with this background knowledge and having a deeper understanding about sound, the formal inquiry commenced. The principal visited the class to explain the students’ role as “sound engineers” and some of the elements that she would like to have designed for the outside space. The design of such sound elements involved students in looking at musical instruments and brochures before discussing and sketching ideas with their partners. Once approved by their class teacher, students constructed their prototypes using several of the recycled materials including offcuts donated from the actual building site such as piping, wood, and guttering. Students tested their prototype before making any final changes and preparing to share at the community expo. Design ideas from sketching an initial idea to producing the final product were presented in their portfolio for display. Parents and the school community attended the expo wherein the students wrote expositions, shared their portfolios, and filmed short statements to convince the principal to choose their design. Following the expo, students had the opportunity to reflect on their learning experience. Their comments included enjoyment in working collaboratively; having fun; being creative; having the opportunity to share their learning; and being proud of their efforts. A photo display was mounted in the front office, and the students presented their models during a whole school assembly.

This was followed by the students sharing and communicating their ideas with the wider school community and then reflecting on their learning. Throughout the process the students created a portfolio containing their questions, design ideas and reflections on their learning. In addition to the student reflections, staff reflections on their learning experiences and the visitor feedback from the “community expo” helped Cara and Mary to reflect on the entire teaching and learning experience. As the School Principal stated,

A learning space designed by students acknowledges their agency. In 2018 our Year 4/5 students designed an internal space. In 2019 the Year 1s created an outdoor musical space. The musical instruments they designed influenced the school’s selection of large outdoor instruments which will be part of the outdoor learning space and musical garden. These students have shown the school community that they love a challenge!

Principal Interview.

And, as Cara commented

The enthusiasm of the dedicated staff and students, and the opportunity for students to share their learning with the community at the learning expo with enthused parents, staff and visitors was inspiring.

In 2020 the STEM focus continued with inquiry-based learning and a continuing focus on real world/authentic problems that students could connect with. For example, after investigating in the importance of being more sustainable with water use, the year 2 students created a water filtering device that could clean water found in the local area, and the year 6 students designed, made, and marketed a working prototype of a solar powered device that could be used in the school.

As Cara stated,

We are looking forward to continuing our STEM journey and have enjoyed the opportunity to be involved in a project that has both strengthened and reinforced our knowledge of STEM. The opportunity to network with teachers and mentors both through the cluster workshops and the mentor meetings gave us the opportunity to share our progress, discover other STEM ideas developed by colleagues and seek feedback to support our inquiry. Engaging in the project also helped us as a school to develop a clear STEM philosophy with a focus on students engaging in learning activities that investigate the world.

Through our work with teachers on developing STEM focused inquiry-based projects, we have found that teachers genuinely attempted to adopt a problem-solving/inquiry-based approach in their STEM focused projects, and that during this their students’ team building and collaboration skills also developed. Additionally, like the findings of [Toshalis and Nakkula \(2012\)](#), students’ communication processes, along with their motivation and engagement were also seen to improve when an inquiry process that required the formulation and investigation of their own questions was prioritized through fostering student agency and the critical analysis of what they had done.

Mathematics and STEM

Inquiry based approaches to STEM create opportunities for educators to create interdisciplinary programs of learning which include components of two or more of the different disciplines. The [National Council of Teachers of Mathematics \(NCTM\) \(2018\)](#) reminds us that in STEM Inquiry programs the curriculum subjects, which in an Australian context are science, mathematics, and technology, often play a different role to the discipline of engineering. Therefore, it is not surprising that the drivers of STEM inquiry in a primary or middle school context are predominantly science, technology, and mathematics. However, these disciplines are generally not prioritized equally due to factors ranging from teacher preferences to teacher confidence in cross-curriculum alignment. As [English \(2016\)](#) highlighted, many STEM initiatives foreground one of the disciplines, typically science or technology and even engineering (not a curriculum subject in Australia), yet mathematics often has limited emphasis or inclusion.

Some argue that mathematics is a core part of STEM because STEM provides a context for engaging in mathematic ideas and concepts. Such a restricted view of mathematics in STEM might in fact limit the opportunity for deep mathematics learning. [Johnson \(2012\)](#) however, argues that the STEM disciplines of science, technology and engineering are inherently connected by the way they require application of mathematics to solve problems. Thus, implying that rather than being a “forgotten” aspect in STEM, mathematics is the lynchpin that holds it all together. [Fitzallen \(2015\)](#), in her exploration of the way mathematics is integrated into STEM programs of learning, discusses the variance regarding the way in which mathematics is included in STEM and notes that in some studies (such as [Hefty, 2015](#)) the effect size for mathematics is low in integrated STEM learning whereas in others there is significant learning in mathematics. From our work with teachers [O’Keeffe et al. \(2021, 2018\)](#), [Panizzon et al. \(2021\)](#), [Scott et al. \(2021\)](#), we found that inquiry-based approaches to STEM resulted in incremental changes in teaching approaches, with students indicating that there was a small but significant (p. 006) decrease in their experiences of the traditional approaches to mathematics teaching and learning ([O’Keeffe et al., 2021](#)). Additionally, students typically reported small, but in some cases significant increase in opportunities to design their own investigations in Mathematics.

As part of one of our STEM inquiry-based projects, student pre-surveys across 30 schools indicated that they were not confident in their Mathematics and Science ability and were even less confident in being able to apply their knowledge of Mathematics and Science ([O’Keeffe et al., 2021](#)). Over 40% of these students surveyed ($n = 644$) were either not confident or were unsure about their ability in Mathematics and Science. However, analysis of the “post” survey data indicated that their involvement in the inquiry-based approach to STEM had had a positive impact on their confidence in their ability in Mathematics and Science. Interestingly, this increase in confidence was more likely among primary school students than secondary school students. Even so, students reported not enjoying mathematics and science, with mathematics presenting as more of an issue than science. Teachers who were involved in these inquiry-based approaches to STEM themselves reported the challenge of integrating mathematics, and with the assessment of mathematics as part of STEM. One factor mentioned across a range of our projects with teachers, both primary and secondary, has been their recognition of the importance of making a sustained and explicit commitment to embracing inquiry-based learning more holistically. This has meant incorporating a range of assessment strategies, such as detailed rubrics; student presentations; and formative interim reports during the inquiry. It has also required a shift from an end-product focus (summative assessment) to continuous assessment of both process and conceptual learning from each of the STEM related disciplines. For example, students might be assessed on their practical work, their reports, how focused their notes were, on group generated posters promoting their designed and constructed product, and so on. Instigating a formative assessment approach allowed a teacher flexibility to address elements of the different disciplines across the range of assessments, and at different times.

Across the STEM inquiry projects [O’Keeffe et al. \(2021, 2018\)](#), [Paige et al. \(2018\)](#), [Panizzon et al. \(2021\)](#), [Scott et al. \(2021\)](#), teachers reported that using a more flexible approach to assessment required investing time in the initial mapping process mentioned earlier, in the development of different assessment strategies, in collaborating with colleagues and collaborating with community/industry personnel. They also found that inquiry-based STEM projects that were authentic for students, that required critical thinking and a need to communicate and collaborate created more opportunities for student centered approaches to teaching and learning. This in turn impacted positively on their pedagogical practices in STEM. As a result, students identified a greater appreciation for the role of mathematics in STEM Inquiry. As one teacher reported,

[we understand] the role of Mathematics within Science a bit better. We’ve gone to lengths to ensure the maths we’re using, it’s not just volumes, it’s not just area, it’s not just taking averages, there’s some actual real maths. That one [exercise] with the pyramids, they (also) need to use trigonometric functions’.

Secondary Teacher.

Like [Shaughnessy’s \(2013\)](#) warning that the “M” in STEM must be made more transparent, our research also found that inquiry projects need to ensure that the connections between the project content/problem and the specific discipline knowledge required, needs to be made explicit for students. This is of particular importance in Mathematics. While teachers may feel that the mathematics embedded in an Inquiry Project is obvious, that is not necessarily so for students, who tend to find it easier to identify and explain the Science and Technology in an inquiry. For example, students in one focus group were clearly able to articulate their learning in science, making note of aspects such as “Rate of decomposition” and “Molecular structure and properties,” and their

learning in Technology, noting examples such as design, 3D printing, using TinkerCad. However, the detail they provided about their mathematics learning was limited. There were however several examples where students were able to explain various aspects of a given process in scientific or mathematical terminology. As one teacher stated,

An upper primary group had made stress balls using cornflour and water. The students were able to explain how the various elements of water and cornflour, when combined and placed in a balloon, could make a stress ball. Non-Newtonian fluids like cornflour are good at absorbing and dissipating energy. Viscosity increases with applied pressure.

Primary Teacher.

Planning a unit of work that focused on mathematics was least evident in all the school STEM inquiry projects that we have engaged with. As many STEM inquiry projects tend to focus on science, it is not surprising that students find it more difficult to articulate their learning in mathematics. When mathematics was included, the mathematics content tended to be focused on measurements, ratios, or data collection. Such limited mathematical inclusions run the risk of reinforcing students' negative views of the potential and power of mathematics to enhance STEM inquiries, with some indicating they didn't learn any mathematics, and some only providing superficial examples, such as "it was kind of basic maths," "didn't use much maths except for measurements." When probed on their mathematical learning during interviews, the students generally struggled to add any more detail and explain what they were learning in undertaking the inquiry, something the teachers also noted in post project reflections. It is also important to note that this was an area of challenge for some teachers. As with any professional learning initiative, teachers were keen that students were engaged and understood the relevance of what they were undertaking. However, a common concern raised by secondary teachers, was the challenge they faced in planning an appropriate level of content for STEM curricula in their "non" disciplines. Some indicated that ideas for "getting started" initially came from a "fun activity" undertaken during current or previous project/interests (e.g., flying drones, coding a game, making a robotic arm), rather than being driven by intended content learning outcomes, and most particularly with the mathematics curriculum. As such, they often felt that what had been addressed was "tokenistic" and were concerned about the depth of learning by students in this discipline. Some examples provided were the inclusion of budgeting elements, business planning, or a survey component without these being relevant to the context of the inquiry. Such superficial inclusions of mathematics have the potential to reinforce [Shaughnessy's \(2013\)](#) concern that "the M will become silent" in STEM.

However, this does not mean that mathematics cannot be effectively learned in integrated STEM inquiry. For example, in several cases there were missed opportunities to extend students' conceptual understanding in mathematics, such as by encouraging them to explain why something had happened, or why they chose a particular approach. An example that clearly reflects this was a group of Year 7 and 8 students who were working on a handheld water filter ([Fig. 1](#)). The students could clearly articulate the scientific principles of their filter and the how the different properties of the materials they had chosen would contribute to filtering the water. In their initial investigations the students were "trying different ratios of materials" however when asked what ratios they had tried and how the different ratios impacted on the pH of the water the students couldn't answer. This was because the task had not required them to record what they were doing and why, and hence an opportunity to extend their mathematical thinking and understanding of ratio was missed. Another example involved prototypes and models that weren't built to scale. It should be noted however, that examples such as these were more frequent in a teacher's first year of a project when they were still grappling with new planning and pedagogical approaches, let alone the complexities of managing space and equipment across multiple sites. This highlights the importance of initiating long-term professional learning projects in schools.

Fig. 1 Example of handheld water filter developed as part of STEM Inquiry project.

Summary

Choosing or negotiating authentic inquiry-based tasks with learners is essential in ensuring that students have an effective STEM focused learning experience. This isn't to say that there are "good" or "bad" tasks. Rather, inquiry-based tasks must be meaningful enough to allow for purposeful investigation and exploration. When STEM inquiries allow student agency, both teachers and students can provide more detailed explanations of the learning across the STEM disciplines.

Our experiences with STEM focused projects within South Australian schools, both primary and secondary, regional, and metropolitan, public, and private, have demonstrated that STEM focused inquiry-based projects create a unique opportunity for teachers to develop topics/projects such as those based on concepts associated with sustainability, eco-justice, critical numeracy and so on. Critically, and foremost, teachers need to be supported in their STEM journey by school leadership and their education systems, as was done for each of the projects that we designed and led. Such support needs to assist teachers to be able to collaboratively plan, share, learn, apply, and reflect on the content and intended learning outcomes, that incorporate a range of assessment strategies, in *each* of the STEM disciplines. Additionally, and fundamental to its success is that teachers clearly articulate the purpose and conceptual relevance of each inquiry to their students.

STEM and STEM education

The acronym STEM refers to the disciplines of science, technology, engineering, and mathematics. Since diverse economic sectors are dependent on the technological innovations occurring in the STEM fields (Orpwood et al., 2012), many countries are prioritizing STEM in education as a strategy to promote sustainable economic development, job growth and competitiveness in the global economy (Carnevale et al., 2011; National Research Council, 2014; Warde and Sah, 2019). While the impetus for STEM in education emerged from economic and political contexts, STEM Education is being repositioned as knowledge that promotes intellectual and social competencies and humanistic goals such as democracy and social justice to benefit society (Bybee, 2013; Park et al., 2020; Zeidler, 2016). Three broad goals for STEM education have been identified as STEM literacy, a STEM workforce equipped with 21st century competencies (e.g., critical and creative thinking, collaboration and communication) and STEM researchers and innovators (Bybee, 2013; National Research Council, 2014). In educational settings, the main goal of STEM education is STEM literacy (Vasquez et al., 2013). Bybee (2013) conceptualizes STEM literacy as involving three aspects: (1) having knowledge, attitudes, and skills to ask questions, problem solve, explain phenomena, and draw conclusions from evidence about STEM-related issues, (2) an understanding of how to use inquiry and design, and (3) as using ideas of STEM to reflect on issues as concerned citizens. Tang and Williams (2019) initiated an empirical analysis of the characteristics of each STEM discipline and demonstrated that STEM literacy is a useful educational construct. Their analysis showed that STEM literacy captures some common practices across the STEM disciplines (e.g., the use of diagrams such as charts and schematics) that can be applied by the general public to understand and engage in civic discussions of STEM issues. The authors, however, argue there is a need to distinguish STEM literacy from the unique skills and knowledge of a discipline such as disciplinary language and ways of interpreting, critiquing, and creating that are not applicable to other STEM disciplines. The unique skills associated with a specific discipline, they refer to as S.T.E.M. literacies. Tang and Williams purport that literacy development in a person integrates the skills and knowledge associated with STEM literacy and individual S.T.E.M. literacies. The challenges arising around discipline specific S.T.E.M skills and common STEM skills, as will be discussed below, has to some extent influenced how STEM Education is implemented in educational settings.

While there is a degree of consensus on what the goals of STEM Education are, there is a lack of consensus on what STEM Education is and what a STEM Education program entails (Holmlund et al., 2018; McLoughlin et al., 2020; Siegel and Giamellaro, 2020). In many countries, such as in Canada and the US, STEM in schools has been operationalized through the disciplinary subjects of science and mathematics with strategies to intentionally integrate concepts and practices of science and/or mathematics with the concepts and practices of technology and engineering (Vasquez et al., 2013). According to Vasquez et al. (2013), the different approaches to STEM education can be represented on a continuum of levels of STEM integration. These authors describe a continuum of STEM integration from multidisciplinary (learning disciplinary knowledge separately but around a common theme), interdisciplinary (applying relevant disciplinary knowledge from two or more disciplines at the same time to understand a concept/topic/issue) to transdisciplinary (applying knowledge from two or more disciplines to a project or to solve a problem). The latter two levels of integration align closely with an integrated STEM approach. An interdisciplinary approach begins with the discipline and integrates other STEM disciplinary knowledge and skills to address issues and a transdisciplinary approach begins with a social issue or real-world problem and draws on knowledge of more than one STEM discipline during the problem solving process to find solutions (Fensham, 2009; Quigley and Herro, 2016). The adoption of an integrated STEM approach does not come without challenges in practice.

Within both the interdisciplinary and transdisciplinary approaches, is an implicit expectation that practitioners have a good knowledge of content knowledge and pedagogical skills of two or more disciplines in STEM. Hence the implementation of an

integrated STEM approach is a challenge for many practitioners at K-12 schools and higher education institutions. Many educators lack knowledge of the content, practices and pedagogy associated with the different STEM disciplines. Studies show that K-12 math and science teachers lacked confidence to teach engineering concepts, and K-12 technology teachers identified limited content knowledge in science and math as barriers to teaching engineering design (Ames, 2014; Kelley and Wicklein, 2009). Teachers are either experts in a single STEM discipline (e.g., math or science) in high schools or may be generalists and teach all subject areas (e.g., elementary school teachers; Park and Ertmer, 2008). Quigley and Herro (2016) found that middle school math and science teachers had difficulties with transdisciplinary STEM teaching because of their desire to place their content specializations at the forefront. The latter may be motivated by the need to meet disciplinary knowledge expectations while trying to make connections across disciplines (NRC, 2014). Research has shown that another limitation of interdisciplinary STEM tasks that included mathematics, was the limited development of foundational math thinking and concepts as assessed by curriculum standards (Tytler, 2020). While interdisciplinary tasks did enhance student interest and enthusiasm for mathematics (Tytler et al., 2019), the smallest gains occurred in mathematics achievement (Williams et al., 2016). Another challenge for teachers is assessing practices and applications of other disciplines which they may have limited knowledge about – for example how argumentation practices in science and math are different (NRC, 2014). Hence, as reported by Siegel and Giamellaro (2020, p. 744),

The adoption of STEM relies heavily on the stakeholders, within their unique context, actively defining an innovation and that practitioners made sense of and connected to STEM based on existing context and practices.

Siegel and Giamellaro (2020) concluded that understanding and implementing STEM is a process that is active, context-based, negotiated, co-constructed and evolving. The implication for practice is that the implementation of STEM is dependent on the different ways teachers implement STEM and this implementation affects student learning of STEM. As reported by the National Research Council (2014, p. 7),

The expertise of educators working in classrooms and in after-/out-of school settings is a key factor – some would say *the* key factor – in determining whether integrated STEM education can be done in ways that produce positive outcomes for students.

Therefore, an important question posed by the National Research Council (p. 10) was: “What instructional approaches or contexts are most likely to lead to student outcomes related to making connections between and among the STEM disciplines?” The NRC conducted a study over 2 years on Integrated STEM Education in K-12 in the US and found that STEM integration that was characterized by explicit support to learn disciplinary knowledge and skill showed promise to increase learning of concepts within the disciplines, especially in engineering and technology. Targeted supports included strategies such as explicit prompts and teacher demonstrations that focused on disciplinary concepts (Schnittka and Bell, 2011).

Given the challenges many teachers face related to lack of disciplinary knowledge in STEM fields, Kelly and Knowles (2016) suggest using “an integrated approach [that] seeks to locate connections between STEM subjects and provide a relevant context for learning the content” and they propose engineering design as an ideal context for integrating STEM because of the “systematic approach to solving problems that often occur naturally in all of the STEM fields” (p. 3). Consistent with the latter, Moore and Smith (2014, p. 5) conceptualize STEM integration as student participation in engineering design in K-12 education and explain:

Integrated STEM education is an effort to combine the four disciplines of science, technology, engineering, and mathematics into one class, unit, or lesson that is based on connections among these disciplines and real-world problems ... with students participating in engineering design as a means to develop relevant technologies that require meaningful learning through integration and application of mathematics and/or science.

The National Research Council (2014) explains further that engineering design, scientific inquiry and problem based learning (PBL) share features that provide relevant contexts to apply STEM concepts. For example, they explain that all three learning strategies are characterized by features such as experiential learning, student centeredness, problems acting as both the focus and stimulus for learning, and self-directed learning.

Robotics and Makerspace activities, which incorporate engineering design, scientific inquiry practices, and PBL have potential to promote interdisciplinary and transdisciplinary approaches to integrated STEM education and provide the context to address practitioner challenges and ease the way to STEM adoption within the curriculum (Bevan et al., 2015; Sullivan, 2008). Robotics and makerspace act as the context to apply knowledge from the four STEM disciplines as students design and construct artifacts/products or create solutions to solve real-world problems. The focus in these two contexts is on STEM: engineering design, technological construction process and discipline specific knowledge and inquiry skills from science and math applied during the activity. The next two sections discuss how robotics and makerspace respectively act as the context for and in support of integrated STEM Education in informal and K-12 education.

Robotics as/for STEM education

Robotics presents an opportunity to learn about the four disciplinary areas of STEM while promoting the learning of competencies and skills such as critical thinking, problem-solving, computational thinking and inquiry (Nugent et al., 2014; Ma and Williams, 2013). Research studies show that robotics supports STEM Education by enhancing STEM content learning and skills, improving interest and motivation in STEM subjects, and broadening diversity and participation of underrepresented groups (Anwar et al., 2019; Benitti, 2012). Specific benefits of educational robotics include enhancing understanding of specific STEM concepts in science and math respectively (Ardito et al., 2014; Park, 2015; Williams et al., 2012), developing science process skills (e.g., Sullivan, 2008) and increasing student engagement, interest, creativity and motivation in STEM courses and careers (Hudson et al., 2020; Miller et al., 2018; Master et al., 2017). Interest in STEM is important as it has been shown to positively influence school achievement (Renninger and Hidi, 2011; Wigfield and Cambria, 2010) and science degree attainment (e.g., Tai et al., 2006). Studies also show that robotics supports the progressive development of skills such as computational thinking (Kazakoff et al., 2013; Sullivan and Heffernan, 2016), metacognition (e.g., La Paglia et al., 2011) and problem solving (e.g., Atmatzidou et al., 2018). The aforementioned benefits of robotics reinforce the use of robotics for and as STEM Education.

Robotics in Informal Science Education settings

Robotics offers a learning context to engage youth in authentic, hands-on, design, creation, and programming using knowledge and skills that engineers and programmers apply. Such programs help students learn scientific and engineering skills that are not easily learned in traditional formal educational settings (Gura, 2012). Robotics programs are commonly implemented by informal organizations such as science centers, scientific organizations and faculties of engineering at colleges and universities as after school programs (Nugent et al., 2010; Williams et al., 2007) and as robotics competitions (Chung et al., 2014; Karp and Maloney, 2013).

Informal Science Education (ISE) programs play an important role in supporting STEM Education. ISE has long been used as the context to promote interest in science and sustain participation in STEM careers among youth and underrepresented groups (Fadigan and Hammrich, 2004; Tytler and Osborne, 2012). A recent longitudinal study (Habig et al., 2020) investigating how an ISE program, conducted at a museum, impacted the STEM trajectories of youth, found that 82.3 % of youth alumni enrolled in a STEM major and 63.1% engaged in a STEM career. The study also reported that the majority alumni in these STEM areas were females and/or members of historically underrepresented racial and ethnic groups. Findings of this study also revealed that the most important ISE program features that contributed to sustained participation in STEM were the provision of multiple opportunities to practice and do hands-on STEM, building social networks and relationships with STEM practitioners such as scientists, and exposure to a variety of STEM areas and careers. However, all students, especially students from economically disadvantaged communities, will not have access to such ISE programs as many programs are scheduled outside of formal school hours, require extra time and may involve additional costs. Hence, including robotics in formal educational settings as part of the curriculum is also needed to promote equitable access so all students can benefit from this STEM approach.

Robotics in formal educational settings

According to Benitti and Spaloor (2017), robotics, which combines technology and engineering principles in real world applications, supports teachers to concretely demonstrate science and mathematics concepts in real-world applications. Scientific inquiry as investigating phenomena to find explanations and engineering design as devising solutions to problems parallels how scientists and engineers engage in knowledge creation and knowledge application respectively (NRC, 2012). In many countries, engineering design is incorporated into the K-12 science curriculum. For example, since 1998, engineering design has been included in the Canadian elementary school science curriculum. In the US, the practices that characterize scientific inquiry and engineering design for school curricular are outlined in the *Framework for K-12 Science Education* (National Research Council, 2012). According to this Framework, there are eight practices considered essential elements of the K-12 science and engineering curriculum: “asking questions (for science) and defining problems (for engineering), developing and using models, planning and carrying out investigations, analyzing and interpreting data, using mathematics and computational thinking, constructing explanations (for science) and designing solutions (for engineering), engaging in argument from evidence, and obtaining, evaluating, and communicating information” (p. 49).

Research (Ziaeeefard et al., 2017) shows that robotics engages students in engineering design practices such as defining the engineering problem (e.g., how does the robot work to solve the problem), proposing the solution to the problem (e.g., how to build the robot), and optimization (e.g., how to improve the efficiency of the robot to complete the task). While there are many practices common to scientific inquiry and engineering design such as stating a hypothesis, designing investigations, repeating experiments, analyzing and interpreting data to confirm or reject the hypothesis, using evidence and evaluating, and communicating results or information, there are differences. For example, how scientists and engineers develop and use models, plan and carry out investigations, and analyze and interpret data are different. Robotics can be used as a real world context to show the different ways scientists and engineers work and is a promising strategy to promote knowledge of technology and engineering in K-8 schools where these disciplines are most underrepresented (Bybee, 2010).

Research also indicates that robotics can provide opportunities for even elementary school students to learn science and engineering concepts and practices earlier than expected and these robotics learning experiences can develop students' confidence and

interest in math, science, and engineering (Park, 2015; Rogers and Portsmore, 2004). An analysis of research studies conducted over 15 years (Bascou and Menekse, 2016) found that “active learning based pedagogies, which were made possible through educational robots, were considerably more effective than pedagogies that passively transmitted information from teacher to student” (p. 6). Active learning pedagogies are student centered pedagogies grounded in constructivist theories of learning that posit that knowledge acquisition or learning involves the personal cognitive construction of knowledge mediated by social interactions (Duit, 1996). The well known 5E Inquiry-Based instructional model is based upon the constructivist theory of learning (Bybee and Landes, 1990) and consists of five phases: engage, explore, explain, elaborate, and evaluate. This model considers students’ prior knowledge with instructor monitoring and feedback and opportunities for student reflection. Robotics activities incorporate many components of the 5E inquiry model. For example, robotics engages students in open inquiry through the use of concrete tools (Sullivan, 2008), has in-built scaffolds such as structured prompts and visuals to guide students through activities (Mitnik et al., 2008) and provides just in time feedback (Sullivan, 2008). Robotics activities, with active hands-on and minds-on learning, can act as a context for inquiry in the STEM disciplines such as science and math. The inclusion of robotics in science or math classes is not consistent and widespread and may be due to a variety of factors. For example, robotics is not an expectation of many K-12 science or math curricula even though robotics lends itself to inquiry-based learning and engineering design and, there are challenges associated with its implementation in K-12 settings.

Implementing robotics in K-12 settings

While robotics has potential to engage students in STEM learning, the gains in learning are not guaranteed just by the simple application of robotics. As reported in a meta analysis of robotics studies by Benitti (2012), most studies indicated gains in student learning of STEM concepts and skills, however, four studies reported non-significant gains in student learning. It is therefore important to recognize that the implementation of a robotics program does not necessarily enhance student learning of STEM concepts (Benitti, 2012; Park, 2015). A number of factors contribute to knowledge gains for students during robotics implementation. For example, one of the factors cited for the low gains in geospatial concepts in the study by Nugent et al. (2008) was the lack of alignment of concepts with topics in the traditional middle school science curriculum. Another factor that appeared to affect student learning from robotics interventions was the length of time for the intervention. Students, participating in a longer robotics program demonstrated significantly greater understanding of STEM concepts and showed higher self-efficacy than students participating in a shorter intervention (Nugent et al., 2010). It was also noted that the shorter intervention did have a positive effect on student attitude—students’ attitudes and interest toward robotics increased. The latter result suggests that shorter robotics interventions can play a role in motivating students and increasing interest in STEM subjects which creates a high degree of student interest and engagement in STEM careers (Nugent et al., 2010; Robinson, 2005; Rogers and Portsmore, 2004).

In a recent meta analysis by Anwar et al. (2019), the authors reviewed 32 studies that involved the use of robotics to enhance construction of knowledge and application in STEM through an active learning process. These studies revealed that robotics did provide experiences that helped students increase understandings required for constructing knowledge and enhanced students’ ability to transfer knowledge. However, the authors also draw attention to the short-term nature of many of the comparative studies and call for more long-term studies to reinforce findings of knowledge and transfer gains. Another meta-analysis of 144 experimental studies investigating the effectiveness of computer based scaffolding on problem centered approaches in STEM education such as inquiry, design, and problem based learning showed that students who received scaffolds did better on cognitive tests than students who did not receive scaffolds and all scaffolding intervention types improved cognitive outcomes (Belland et al., 2017). Providing scaffolding (e.g., just-in time tutorials, lessons, immediate feedback and debriefings) during the problem-solving robotics activities and providing different activities to differentiate for different levels of content knowledge and problem solving skills, helps students make connections to scientific and engineering concepts (Williams et al., 2007). Other factors that enhanced STEM learning during robotics activities were large physical spaces for students to engage in experimentation and testing, small student groups of 2–3 pupils per robotics kit, and accommodating for diverse student interests and learning styles – e.g., providing multiple entry points into robotics (Lindh and Holgersson, 2007; Rusk et al., 2008).

The literature also suggests that the extent and quality of robotics learning is dependent, to a larger degree, on the teacher. Studies have identified the following characteristics of a teacher that impact the successful implementation of robotics:

- Comfort and skill level using robotics software for programming (Vollstedt et al., 2007),
- Attitude of the teacher – how to motivate students and promote positive attitudes toward the use of robotics (Lindh and Holgersson, 2007)
- Knowledge of appropriate pedagogical approaches to teach STEM concepts using robotics such as robotics enhanced inquiry-based learning (REIBL; Park, 2015) or engineering design (Rogers and Portsmore, 2004).
- Knowledge of specific scaffolding to show how robotics activities relate to science and engineering processes and to curriculum learning goals and subjects (Nugent et al., 2010).

Successful robotics implementation as and for STEM in K-12 settings depends on the teacher’s knowledge of robotics, STEM content, and student centered pedagogy and their comfort level to implement robotics based activities within classrooms. Teachers must be provided with professional development support that is effective at building content and pedagogical knowledge, and the technical skills for using robotics and other technology to promote student learning of STEM. Professional development to enhance teacher self-efficacy to integrate robotics in instruction and engage in curriculum design (Anwar et al., 2019),

as well as technical support during implementation (Rogers and Portsmore, 2004) are prerequisites for effective robotics implementation in K-12 settings.

Makerspace as/for STEM education

The maker movement arose from the “Do-it-Yourself” culture comprised of crafters, hackers, tinkerers, quilters and other makers who collectively became known as makers (Bevan, 2017). Dougherty (2013), the founder of Make Magazine describes makers as enthusiasts “who played with technology to learn about it” (p. 7). The distinction of the maker movement from the prior activities of crafters, tinkerers and inventors is the prevalent use of digital technologies such as 3D printers and microcontrollers, and the online sharing and collaboration that characterizes current maker communities (Halverson and Sheridan, 2014). Martin (2015), drawing from various definitions, defines making “as a class of activities focused on designing, building, modifying, and/or repurposing material objects, for playful or useful ends, oriented toward making a ‘product’ of some sort that can be used, interacted with, or demonstrated” (p. 31). Although there is not one unified definition for makerspace, a common feature is the idea of it being a shared space or “gathering point” where people can come together and work on projects, alone or with help from persons who may be knowledgeable in the area of exploration, with access to various tools and new technologies (Maker Media, 2013, p. 1). The nature of making therefore resonates with the T and E in STEM. Engineers design, test, modify, develop and conduct failure analysis of a variety of products where technology is used in the manufacturing and construction process to create technological innovations (Lucas, 2014). Similarly, makers create and problem solve in spaces called makerspaces, hackerspaces, tinkering studios and playlabs where they come together to create and design technological products (Anderson, 2012). The focus on design activities in makerspaces align with many science education goals (e.g., Next Generation Science Standards, NGSS Lead States, 2013; The Ontario Curriculum Grades 1–8, Science and Technology, Ministry of Education, 2022) that incorporate engineering design and technology. Halverson and Sheridan (2014), however, caution against limiting maker to K-12 learning activities as this would limit the democratizing potential of maker as a way to provide access to the power discourses usually employed by producers of artifacts using 21st century technologies.

Makerspace in informal educational settings

Making in informal spaces is a spontaneous activity and stems from people’s enthusiasm, passion and interests and involves making things, taking them apart and remaking to create new innovations and products (Dougherty, 2012). Many community spaces such as libraries, museums, and science centers have created makerspaces to promote active participation and hands-on learning in exhibits related to STEM and art (Bevan et al., 2015; Gutwill et al., 2015; Kafai et al., 2014). According to Educause (2013),

Makerspaces are zones of self-directed learning. Their hands-on character, coupled with the tools and raw materials that support invention, provide the ultimate workshop for the tinkerer and the perfect educational space for individuals who learn best by doing ... they promote multidisciplinary thinking and learning, enriching the projects that are built there and the value of the makerspace as an educational venue (p. 2).

The unique nature of makerspaces derives from addressing what the community needs (Hughes, 2017) and therefore building or creating a space that suits the interest of the community of makers using the makerspace is necessary. According to Bullock and Sator (2015), making is:

A participatory activity that draws the whole body of the maker into the creation of the project and the resulting artefact(s) represent the creative process of design, social interaction, and ethos of sharing inherent in the personal and collective learning process. (p. 70)

Informal makerspaces are self-directed and involve makers across age groups. Sheridan et al. (2014) examined three makerspaces in informal settings comprised of makers who were adults, families and youth. Their study identified the following characteristics common across the three makerspaces: diverse tools, materials and processes; makers worked across disciplines in terms of the processes engaged in and the products made; formal pedagogical structures such as computer workshops or skill demonstrations were incorporated with voluntary attendance; mentoring and leadership roles were assumed as needed; learning was embedded in the process and product; members found projects and products to work on and engaged in the design process; and creations and products were shared.

A few studies have investigated STEM related, informal makerspaces. Bonnette et al. (2019) conducted a study with 983, sixth grade students to explore the relationship between participation in informal science activities and children’s fascination/interest in science. Their findings indicated that “informal experiences are positive predictors of fascination. Children who get involved in informal science before middle school and stay involved have a higher fascination, which in turn predicts greater involvement in informal science during the school” (p. 1636). Other research also suggests that engaging in maker-centered learning activities may encourage more students to pursue learning and career pathways related to STEM content areas (Bevan et al., 2014; Hsu

et al., 2017). Fostering student interest and participation in STEM is one of the goals of STEM educators in K-12 formal learning environments. However, tensions exist between making practices and formal educational practices. The question to ask is: how can the features of informal makerspaces be translated into formal educational environments in ways that reflect the unstructured, creative, and collaborative nature of learning in makerspaces compared to the structured, curriculum aligned learning in formal K-12 educational environments?

Makerspace in formal educational settings

Making in formal educational settings is associated with the theory of constructionism (Papert, 1991) where the learner builds personal, concrete knowledge through construction of artifacts chosen by the learner. The four elements of a maker mindset outlined by Martin (2015) provide a workable framework for designing makerspaces in education that align with constructionism. Martin proposed that makerspaces be characterized by the following: (1) being playful – activities selected are those that learners find fun and playful; (2) being growth oriented – provide free choice of activities to enhance skills consistent with strengths of learners; (3) failure-positive – make failure an option and encourage students to use it to adjust, learn and create; and (4) collaborating and sharing – learners work together to discuss ideas and solutions to generate new knowledge and products. These makerspaces therefore provide a space and an opportunity for students to work collaboratively with others to design and create and use trial and error to solve problems through several iterations. Choice in activities provides learners with a degree of agency, similar to informal makerspaces, and promotes access to all learners by offering multiple paths to learning (Martinez and Stager, 2013). Studies show that well designed makerspaces in formal educational environments allow students to experience learning in new or different ways and cater to a range of different learning styles (Blackley et al., 2017; Sheffield et al., 2017) and contribute to an equitable learning space (Martin et al., 2018). A STEM makerspace is therefore another viable strategy to add to the repertoire of hands-on, concrete, inquiry based activities already being implemented in formal science and mathematics classes.

Implementing makerspace in K-12 settings

The formal implementation of a makerspace approach as a pedagogical strategy in K-12 schools is in its infancy. While Martin's (2015) framework provides a guide for creating a maker experience in formal educational settings, it does not address how the goals of formal curriculum are incorporated into makerspace experiences and what skills educators need to be able to implement makerspaces for effective student learning. With respect to the formal school curriculum, in integrated STEM education, learners draw on knowledge and skills from the different STEM disciplines during learning. The latter is congruent with a makerspace approach that deliberately sets student learning in contexts that draw on skills and knowledge from the STEM areas "to create, construct and critique a product that has one or more engineering design elements" (Sheffield et al., 2017, p. 152). Sheffield et al. (2017) argue that the makerspace approach can be a robust pedagogical strategy when strong and explicit connections are made between the making activities and resultant product and curriculum standards of the different STEM areas. Ensuring that relevant curriculum connections are made during the makerspace activity for students is dependent on the pedagogical knowledge and skills of the classroom teacher or educator. Some teacher education programs are introducing makerspace as an approach to teach STEM. Blackley et al. (2017) examined how preservice teachers learn to teach STEM through a makerspace type activity. A small group of preservice teachers (PSTs) participated in a STEM makerspace workshop where they were mentored by engineering students and learned how to design and create an engineering artifact. An important component of PSTs preparation was also learning pedagogical strategies to manage groups, ask questions and make connections to the science concepts related to the artifact. PSTs then worked with 3–6 elementary students in a makerspace activity at a school and provided students with the design task and materials to plan and create the product. The findings of this study with PSTs indicated that maker activities, when introduced into formal educational settings such as classrooms, which are constrained by curriculum standards and formal assessments, require pedagogical scaffolding from the teacher for effective student learning. Scaffolding during maker activities such as teacher questions, is necessary to show connections between the inquiry or design process and knowledge to be learned (Blackley et al., 2017; Darling-Hammond, 2008). Studies (e.g., O'Brien et al., 2016) also suggest that effective implementation of makerspaces requires teachers to be knowledgeable at facilitating less structured instructional strategies and being responsive to the spontaneous nature of makerspaces.

In relation to effectiveness for student learning, Halverson and Sheridan (2014) questioned whether making really improves STEM learning. Recent research shows that STEM makerspaces in the school curriculum have potential as an instructional strategy to support integrated STEM education and the acquisition of 21st century learning skills. In a meta analysis of STEM makerspaces in K-12 education (Schad and Jones, 2020, p. 69–70), eight of 14 studies "suggested benefits for maker-centered learning for STEM content areas" that included "improved motivation, positive attitude toward STEM subjects, and improved learning outcomes in specific content areas." Other outcomes of maker-centered learning revealed by the findings of the meta-analysis were in the areas of equity, creativity, and independent thinking. There are, however, very few studies that have quantitatively investigated the effect of STEM makerspaces on the learning of STEM concepts. Litts et al. (2017) and Jaipal-Jamani (2021) found that STEM makerspaces did result in statistically significant improvement in learning of targeted STEM concepts (e.g., knowledge and design of circuits in Litts et al. study; knowledge of gears in Jaipal-Jamani study). In another recent study, Sheffield et al. (2017) investigated how a makerspace engaged females ($n = 71$) in STEM education at an elementary girl's school. The results showed the potential for a makerspace approach to shift the focus of STEM as a cognitive endeavor for conceptual learning to STEM as inquiry leaning with intrinsic affective and motivational factors.

Successful makerspace implementation as and for STEM depends on the pedagogical skill and comfort level of the teacher to take on the role of facilitator of learning and embrace the flexible nature of the role of teacher and students. Teachers should be provided with exemplars of effective STEM makerspaces and the pedagogical strategies to facilitate learning that suits the needs of individual learners, give students choice, and enables student ownership of learning, yet at the same time, can be assessed for integrated STEM curriculum outcomes. As Fleming (2015, p. 13) succinctly advises, “Talk to your students. They are your stakeholders. Invite students to discuss their interests and share their opinions. This model of integrated decision making, focused on the goal of maximizing the impact of your makerspace, will help ensure a student-centered learning environment”.

Conclusion

Robotics and makerspace are robust instructional approaches that support STEM in different ways such as motivating learners to engage in STEM learning and pursue STEM careers, to improving understanding of concepts and practices in the different STEM disciplines. The literature shows that both instructional approaches involve the learner actively participating in knowledge creation, design, and hands-on construction of artifacts through inquiry, PBL, and engineering design, while drawing on the knowledge and skills from the disciplinary areas of STEM. These are viable instructional strategies to incorporate into disciplinary subjects such as math and science to promote integrated STEM education through lessons or an integrated unit topic. These two approaches can also be used as independent contexts to promote integrated STEM curriculum outcomes. Robotics and makerspace approaches are also grounded in constructivism and constructionism learning theories and can be readily incorporated into preservice teacher education and inservice teacher professional development. Teachers who have been introduced to these approaches enhance the degree of scalability to integrate it across K-12 education.

Widespread implementation of robotics and makerspace in many countries may be limited as it is contingent on funding. Another challenge to implementation arises when engineering design is the central activity in robotics and makerspace experiences. Students may be subject to some of the challenges experienced by students in engineering design. Three challenges that students experience during engineering design that will also apply to integrated STEM learning with robotics and makerspace are cognitive limits of attention and memory, learning from real world solutions and making connections between multiple representations (National Academies of Engineering and Medicine, 2020). The National Academies of Sciences Engineering and Medicine (2020) went on to state that “repeated experience with ideas that cross STEM boundaries in the context of engineering design activities can reduce challenges related to cognitive limits, real-world problem solving, and multiple representations” (p. 61). They suggest the following strategies for how educators can alleviate these three challenges: scaffolding design tasks from well-defined to moderately ill defined to minimize cognitive load, providing just-in time knowledge of science and math concepts to show connections to the real world, and highlighting how models used as representations in the different STEM field are similar and different.

Current approaches to STEM Education increasingly conceptualize STEM as an integrated field where the knowledge and practices from the different STEM disciplines are applied to solve real world problems which parallels how professional engineers and scientists draw on multiple STEM disciplines to find solutions (Czerniak and Johnson, 2014; National Research Council, 2014). While educators implement integrated STEM programs within the parameters outlined in country, state or provincial curriculum standards, the emergence of new careers and multidisciplinary, innovative fields that require knowledge of crosscutting STEM concepts and its applications (e.g., bio-engineering, artificial intelligence, and gene editing), point to the potential for STEM to be enacted as a distinct field. The literature suggests that robotics and makerspaces can act as and for STEM education. When the two approaches are used in disciplines such as science and math they are support for STEM education (interdisciplinary and transdisciplinary STEM approaches). When robotics and makerspace act as the context for STEM outcomes such as bioengineering, they can be conceptualized as STEM education.

Definitions

STEM Education: is applying the disciplines of science, technology, engineering and mathematics through multidisciplinary, interdisciplinary and transdisciplinary learning approaches.

Integrated STEM Education: is a learning approach that involves understanding a concept, solving a real world problem or designing and creating an artifact by applying the knowledge and practices/skills from the different STEM disciplines.

Multidisciplinary STEM Learning: is when disciplinary knowledge and skills are learned separately but around a common theme/topic.

Interdisciplinary STEM Learning: is when knowledge and skills from two or more disciplines are applied at the same time to gain understanding of a concept or topic.

Transdisciplinary STEM Learning: begins with a real world problem or project and knowledge and skills from two or more of the STEM disciplines are applied to solve the problem/project.

STEM Literacy: is having knowledge, attitudes, and skills to ask questions, problem solve, explain phenomena, and draw conclusions from evidence to reflect and make decisions on STEM-related issues.

Makerspaces: are physical spaces where community members create, design, make and repurpose artifacts or engage in projects using physical and digital technologies.

Introduction

In a 2019 commentary, we reinforced the argument that models and modeling could serve as a bridge between the STEM subjects in educational practice (Hallström and Schönborn, 2019). This synthesis emphasized that models and modeling are central to fostering authentic STEM education. The subjects of science, technology, engineering and mathematics are often subsumed into the notion of “STEM”, an acronym used particularly in the last two decades to define content, craft curricular goals, define educational policy and/or motivate political agendas. However, a precise interpretation and operational definition of STEM remains elusive (Breiner et al., 2012) with various camps of scholars suggesting that it is often used in far too general or in far too specific terms (e.g., Henderson et al., 2017; Tang and Williams, 2019). Another saliently discussed attribute is the relative contribution of each “S”, “T”, “E” and “M” subject to the overall STEM construct, with contemporary developments also advocating the inclusion of an “A” for artistic subjects (STEAM), and “i” for information technologies (iSTEAM). Such discussion calls for further and clearer considerations of the nature, roles and implementation of STEM, and how the subjects can be meaningfully linked. In this regard, models and modeling act as point of departure for linking the STEM subjects, thereby contributing to the discussion of the meaning, integration and application of STEM education.

Models and modeling are crucial for solving problems, making predictions, and communicating concepts and constructs (e.g., Müller, 2009; Vincenti, 1990). Models clarify aspects of reality and range from simple conceptual diagrams and early prototypes to advanced mathematical models and machine learning algorithms. Therefore, the competencies needed to create, use, apply, evaluate and revise models are necessary for gaining an in-depth understanding of scientific practice, technological and engineering design, and mathematical tools (Schwarz et al., 2009).

In this article we elaborate upon the nature, roles, and implementation of models and modeling in STEM education, by posing the following questions:

- What is the nature of models and how are they represented?
- What are the roles of models in relation to specific modeling processes, knowledge and skills?
- How can models and modeling be implemented in STEM education?

In pursuit of implementing models and modeling across the four STEM disciplines, the relationship between the nature, roles and implementation of models should be seen as being both intertwined as well as informing one another. The following sections unpack these three key aspects of models and modeling in STEM education by responding to each of the questions that frame the article.

The nature of models and their representation

According to Gilbert et al. (2000), models are *ubiquitous representations of phenomena* such as objects, ideas, concepts, systems, events, and processes. Models describe, explain, construct, and predict phenomena by organizing relevant information, generating hypotheses, and explaining how information may be related (Brady et al., 2015; Lesh et al., 1997, 2013). In doing so, models communicate a simplified version of reality through concrete, conceptual, and formal/symbolic depictions (de Vries, 2013). In this regard, models portray entities in smaller (e.g., a spaceship blueprint) or larger (e.g., a coronavirus diagram) visual forms than the actual represented phenomenon, as abstractions (e.g., force field arrows), or as depictions of concrete and abstract entities (e.g., augmented predicted visual path of a photographed projectile) (Gilbert et al., 2000). Furthermore, models represent dynamic systems such as cause-and-effect relationships as well as in coordinated depictions where the system is communicated as more than the “sum of its parts” (Zawojewski et al., 2008; Diefes-Dux et al., 2008).

Different *modes of representation* are used to communicate a model (Schönborn and Anderson, 2009). Herein, a model can be expressed in at least five different modes of representation, namely concrete (e.g., 3D physical models), verbal (e.g., spoken or written description of model entities); symbolic (e.g., chemical formulae and algorithms), visual (e.g., diagrams and animations), or gestural (e.g., bodily representation of model entities) (Gilbert, 2004). While in science education models are often communicated through concrete, visual, verbal, mathematical, or gestural representations, in technology education models often include iconic (e.g., a sketch), analogue (e.g., simulation), and symbolic (e.g., mathematical) models (Davies and Gilbert, 2003).

Models in science are often central to knowledge building, and fundamental for providing explanations and predictions. Scientific models can comprise consensus models (used in research), which in turn serve to illustrate the nature of science, or historical models (replaced by revised models over time) (Justi and Gilbert, 2002). Nia and de Vries (2017) consider models as “techno-scientific artifacts”. Herein, they have an intrinsic nature, intentional nature, as well as an intrinsic-intentional interconnection. In this regard, Nia and de Vries (2017) have proposed a framework for the “dual nature” (cf. de Vries and Meijers, 2013) of models which may be applied across the STEM subjects. Nia and de Vries (2017) describe the “intrinsic” nature of models as concerning the material structure and form of models, whereas the “intentional” nature of models concerns their purposes or functions, that is, whether they are used for exploration, design or communication. In technology and engineering, knowledge can be developed by constructing and manipulating models, wherein models are used to comprehend design concepts and optimize prototypes (Citrohn and Svensson, 2020; France et al., 2011; France, 2018). In mathematics, a model can be defined as the combination of an extra-mathematical domain, a mathematical domain, and the translation between the two (Niss, 2012).

Roles of models in relation to specific modeling processes, knowledge and skills

Justi and Gilbert (2002) have advocated that models and modeling play a central role both in *learning science* and *learning how to do science*. The modeling process includes determining the purpose of the model, which often includes formulating a mental model of the phenomenon, and ascertaining in what mode of representation (e.g., visual, concrete or symbolic) to express the model. Subsequently, while “testing” whether a model satisfies its foreseen purpose, the modeller infers the scope and limitations of the model.

Regarding the specific roles of models for learning science, Gilbert (2004) states that students should understand what a model is; understand the entities that a particular model represents and how these entities interact with each other; mentally visualize models; display visual literacy skills associated with interpreting models; understand analogy and metaphor in relation to describing model components; and, understand how a model can be used. According to Gilbert et al. (2000) modeling can include several different model types with different roles: mental models (cognitive representations); expressed models (available for others to interpret); consensus models (expressed models that gain acceptance); scientific models (tested expressed models that become predictive tools); historical models (exist in a context and perhaps later displaced); curricular models (historical models in curricula); teaching models (aid interpreting historical and curricular models); and, hybrid models (coordinate scientific, historical or curricular models).

It follows that two roles of modeling in science and design & technology education are modeling ideas in the mind – communicating with oneself – and modeling ideas in the world – communicating with others. The modeling process includes having experience of the phenomenon or problem; formulating suitable metaphors and analogies to express the model; visualizing the outcome of the modeling process; producing a representation of the model, and, evaluating the scope and limitations of the produced model (Davies and Gilbert, 2003).

In technology and engineering education, models support development of theories and artifacts through manipulation (e.g., concrete models) and mental exploration (e.g., conceptual models, sketches). Furthermore, the intrinsic and intentional nature of models in technology and engineering can support building, revising, and communicating knowledge and artifacts related to pedagogical use (e.g., educational models); procedural use (e.g., computer-aided design); and, decisional use (e.g., climate change models). The intrinsic-intentional interrelation of models informs design (designers’ and users’ points of view); simplification (abstraction and idealization); iterativity (trial and error); and, adequacy (judging appropriateness and effectiveness) (Nia and de Vries, 2017; de Vries, 2013). Another aspect of modeling in technology and engineering education is functional modeling, which concerns the development of a design concept and prototyping of the realized outcome, often as an artifact/system. Technological modeling thus provides epistemic strategies for reinforcing that the technological outcome is “fit for purpose”; the purpose is a designed intervention where the outcome is judged by a successful function (France et al., 2011; France, 2018).

In engineering education modeling processes are often similar to that of technology education, but principles from mathematics education for so-called model-eliciting activities (MEAs) may also include model construction, reality, self-assessment, model documentation, model shareability and re-usability, and production of an effective prototype (Zawojewski et al., 2008; Diefes-Dux et al., 2008). Model-eliciting activities (MEAs) in mathematics and engineering education thus include posing the following questions: is the situation authentic? (the reality principle); is the construction or modification of a model required? (the model construction principle); are there clear criteria for assessing the usefulness of the model? (the self-evaluation principle); does the model apply to multiple situations? (the model generalization principle); and, will the solution provide a useful prototype for interpreting other similar situations? (the simple prototype principle) (Brady et al., 2015; Lesh et al., 1997, 2013).

Implementation of models and modeling in STEM education

Strategies for teaching models and modeling in STEM education

To promote a model-based teaching approach, science and technology educators need to communicate to learners what representational components make up a model, demonstrate the scope and limitations of different models, adapt model usage depending on the content taught, and, design meaningful activities that include learners' active model construction (Gilbert, 2004). Justi and Gilbert (2002) suggest the following modeling strategies during teaching: communicate the purpose of a particular modeling activity; provide an authentic experience of the phenomenon being modeled during any practical work; specify the model source; support the mental imagery of a particular model; and, show relationships between different modes of representation of the model (cf. Davies and Gilbert, 2003). It follows that modeling in science and technology involves both a developmental cycle where iterative changes are associated with the produced model, a "fitness for purpose" where a certain specification is envisioned, as well as, a visualization of the intended outcome of the process. For Gilbert et al. (2000), teaching models and modeling contributes to learning because mental modeling is central to understanding. Moreover, expressing and testing models also reflect the "doing" of science, and understanding science relies on interpreting scientific and historical models.

According to de Vries (2013), fusing modeling and design activities enhances STEM learning since design connects scientific, technological, engineering and mathematical components. In addition, modeling activities provide a bridge between a practical scenario and required mathematical analytical tools to model different aspects of reality. In particular, this is the case in problems when understanding reality (science) and manipulating reality (technology and engineering) are foreseen. Developing students' conceptual understanding of modeling and their intrinsic-intentional perspective of models, can foster an enhanced individual modeling ability. In this way modeling can be used as a pedagogical strategy to support STEM learning (France et al., 2011; France, 2018; Nia and de Vries, 2017).

Effective teaching of models and modeling requires paying concerted attention to the design of activities, with adequate time for the activities to be realized (Niss, 2012). In mathematics, students should be provided with an opportunity to experience how mathematical models come to be, and interrogate the trade-offs involved in developing a mathematical model, including assessing the limitations and strengths of different models. When students engage in model-eliciting activities to assess and monitor their own work using authentic tools, they induce the construction, modification, and refinement of powerful conceptual models. Overall, modeling abilities in STEM can be developed along various dimensions that include: from concrete to abstract, from specific to general, from local/refined to global, or from intuitions to formalisations (Brady et al., 2015; Lesh et al., 1997, 2013; Zawojewski et al., 2008; Diefes-Dux et al., 2008).

Integration of models and modeling in STEM curricula and practice

According to Gilbert (2004), integrating models and modeling can increase the authenticity of STEM curricula by explicitly training science teachers in the nature and role of models. Integrating models and modeling in STEM curricula can be promoted through pupils learning to use models, revise models, reconstruct models, and construct models *de novo*. Pre- (and in-) service STEM education should also focus heavily on unpacking the nature of a "model" and how to use different models in different contexts (transfer). This can be promoted by following the historical sequence of model development in a certain topic area as a means of cognitive reconstruction in modeling, and, providing skills for evaluating the strengths and limitations of models (Justi and Gilbert, 2002).

Furthermore, implementing models and modeling to embrace STEM education requires considering the importance of the learning context - curricula need to be enterprising, effective, of good quality and personally relevant (Margot and Kettler, 2019). Such curricula will allow learners to perceive relationships between science and technology content while applying knowledge in real-world problem solving (Davies and Gilbert, 2003). Models and modeling should therefore be viewed by educators and curriculum developers as a valuable bridge between science, technology, engineering and mathematics, which in turn, may promote authentic STEM education. Furthermore, there must be opportunities for students to develop activities to find solutions to, and make informed decisions about real-world issues by integrating both science and technology concepts (Gilbert et al., 2000).

For de Vries (2013), the encompassing facets of modeling allow it to be integrated at various points of student development in STEM curricula. Primary students could, for example, be provided with early experiences of modeling through concrete models, whereas secondary students could engage with formal aspects of modeling, which include nature, types and functions of models and modeling. The intrinsic, intentional and intrinsic-intentional perspective of models can, according to Nia and de Vries (2017), be used to analyze curricula and policy documents on the integration of models and modeling. These perspectives are a potential benchmark of what a curriculum should contain with respect to models and modeling in the STEM subjects. Moreover, modeling can support the development of an understanding of the nature of technology and the nature of science both as separate domains, but also in relationship with one other as well as engineering and mathematics (France et al., 2011; France, 2018).

According to Niss (2012), teaching about modeling should be used to support students' concept formation and sense-making in mathematics, especially when it comes to the transfer to authentic problems. Thus, modeling requires students to actively engage multiple skills (Niss, 2012). Implementing models and modeling in authentic learning programmes can help students construct, modify and refine conceptual models that are applicable not only to mathematics but also to other modeling adaptation activities in engineering, technology and science (Brady et al., 2015; Lesh et al., 1997, 2013). In this way, students are potentially better positioned to understand the strengths and weaknesses of a conventional model, and better prepared to apply, adapt, and even create new models for novel and similar situations, across the STEM subjects (Zawojewski et al., 2008; Diefes-Dux et al., 2008; Kertil and Gurel, 2016).

Conclusions and implications for STEM education

This article has elaborated upon the nature, roles, and implementation of models and modeling in STEM education. Regarding the nature of modeling, although models and modeling differ slightly between the STEM subjects there are some clear similarities, for example, concerning visual models and representations (e.g., Tang and Williams, 2019). Exploring these similarities and bringing differences to light could strengthen STEM education and STEM literacy. Modeling is often about representing simplified versions of reality that take on concrete/physical, conceptual, verbal, gestural or symbolic/mathematical forms (Gilbert, 2004). Models are therefore representations of ideas, objects, systems, events, or processes which are central in the STEM disciplines. At a conceptual level, models are even systems of description in themselves; for explaining, constructing, modifying, manipulating and/or predicting a complex series of experiences. Models thereby help to organize relevant information so as to generate or (re)interpret hypotheses about given situations, designs or processes, or explain how information is related, something which is at the core of all the STEM subjects.

Given the above, we must also be cognisant of the influence of the rapidly developing digital landscape on models and modeling in STEM education. Notably, artificial intelligence (AI), neural networks and machine learning are changing the way models are designed and how modeling is carried out, because some of the modeling is now done not by humans but by computers (Campbell, 2020; Carr, 2015; Wiberg et al., 2019), which are also “learning” to be more proficient modellers. Furthermore, models are increasingly becoming digital and mathematical in conjunction with more complex technological systems, which will also have repercussions on the field of STEM education; if machines learn to model increasingly complex systems, humans may become less involved in, or even lose some of the control over, STEM projects (cf. Hallström, 2022).

When it comes to the roles of models and modeling in STEM education, models support design of artifacts and theory development through manipulation (e.g., concrete models) or mental exploration (e.g., conceptual models, sketches) (de Vries, 2013), and, in the latter case, modeling ideas in the mind for communicating with oneself and modeling ideas in the world for communicating with others (Davies and Gilbert, 2003). Some of the primary skills associated with modeling include: understanding what a model is and how to use it; carefully defining the context of the modeling process; mentally visualizing a model outcome; deciding what mode of representation to express the model; and understanding how a model can be constructed, interpreted, evaluated and revised. A critical ability is also being able to assess the strengths and limitations of a particular model (Schönborn and Anderson, 2009).

Concerning the implementation of models and modeling in STEM education, a lot of evidence points to the relevance of including modeling in authentic engineering design projects. In such engineering projects students will formulate scientific and mathematical models and algorithms to optimize their designs, which are tested with engineering prototypes and functional models. Hence, new knowledge is developed not only about science, mathematics and technology but also about the engineering design process itself; students are required to apply existing knowledge about, for instance, modeling previously learnt in science, technology and/or mathematics (Ammon, 2017; de Vries, 2013; Hallström and Ankiewicz, 2019; Kertil and Gurel, 2016).

Modeling is an indispensable feature of STEM education (see e.g., Banks and Barlex, 2014; Gilbert, 2004; Williams, 2017). Recent studies show that there are advantages in teaching and learning modeling as an integrated STEM literacy. For instance, Krell and Krüger (2017) have shown that STEM students have more advanced “meta-modeling knowledge” than students of other, single disciplines at the tertiary level. Additionally, models and modeling are often seen as a “language” of pursuing an integrative STEM literacy (e.g., Kertil and Gurel, 2016). Albeit so, further research is needed to ascertain how modeling can be developed to purposefully and systematically interconnect the STEM subjects.

In conclusion, this article emphasizes that modeling activities can serve as an important path toward authentic STEM education (e.g., France, 2018; Gilbert et al., 2000). In addition, models and modeling can be used as a vehicle to foster STEM literacy and the transfer of knowledge and skills between STEM subjects (e.g., Niss, 2012). To accomplish this, teaching must take into account modeling frameworks that are based on authentic STEM practices (Breiner et al., 2012). In pursuing this vision, it must be realized that integrating science, technology, engineering and mathematics remains a complex challenge that calls for what Kelley and Knowles (2016) term “a new generation of STEM experts” (p. 1) that can navigate the future expected transitions between the STEM disciplines. Finally, in order to implement and fulfill an integrated STEM literacy, it is crucial that model-based pedagogies intended for STEM education classrooms are empirically investigated and evaluated in real education contexts (Margot and Kettler, 2019).

Introduction

The *Framework for K-12 Science Education* (Framework; NRC, 2012) presents a new vision of science teaching and learning in which students are to develop knowledge to make sense of phenomena or design solutions to engineering problems. Because of the uniqueness of what the Framework and the resulting Next Generations of Science Standards (NGSS; NGSS Lead States, 2013) proposed, districts are currently grappling with finding ways to address the NGSS at the elementary level. In this paper, we present one promising solution.

One of the most significant—and challenging—innovations put forth in the Framework and NGSS is a call for “three-dimensional science learning.” Three-dimensional science learning means that students use science and engineering practices, core scientific ideas, and crosscutting concepts that span science disciplines together in an integrated manner to explain phenomena or solve problems. For example, to figure out why some bird species prefer wetlands over prairies, a student would need to use science and engineering practices like carrying out an investigation and analyzing data of a bird’s habitat, while thinking about the phenomenon through the lens of crosscutting concepts like systems and cause and effect, and also applying core ideas about ecology such as interdependent relationships.

Project-based learning (PBL) is a curriculum approach that shows promise in creating environments for meaningful student learning, including three-dimensional science learning (Miller and Krajcik, 2019; Miller et al., 2021b). Researchers describe PBL in different ways, but they always include the following features: (1) An artifact that drives and culminates a cycle of investigation,

(2) Driving Questions that motivate practices and are answered by the artifact, and (3) Student learning has authentic and student-centered application (Barron et al., 1998; Krajcik and Blumenfeld, 2006).

As part of a large design-based research project, our team designed upper elementary project-based learning environments that extended our vision of PBL to three-dimensional learning. Our task was to develop and refine units of instruction that would provide evidence of the value of PBL in promoting three-dimensional science learning and community. This paper reports on the design cycles that led to our final third and fourth grade products, prior to an efficacy study and the testing of fifth grade materials.

Related research and theoretical foundation

Promise of project-based learning for supporting student learning

Project-based learning (PBL) has its roots in the progressive era with Dewey (Dewey, 1902), who advocated a student-centered education approach. Instead of lecture, Dewey believed learning should have practical meaning and direct application. He moved away from teacher-centered to student-centered teaching and learning. Dewey advocated for an educational approach that would engage students in experience as active participants in learning, an approach that he argued promoted their interest and motivation (Weiss et al., 2005).

Despite evidence of the promise of PBL as an effective curricular approach for students, PBL is under researched, especially in elementary education (Duke et al., 2021). Studies support PBL as motivating for students (Harris et al., 2015; Miller et al., 2021a), and that PBL enhances subject matter learning (Condliffe et al., 2017; Geier et al., 2008; Miller et al., 2020b). PBL is defined differently across scholars and program designers (Barron et al., 1998; Blumenfeld et al., 1991), yet all iterations draw on situated cognition (Brown et al., 1989) and constructivism (Bransford and Schwartz, 1999). The lack of consistency in definitions of PBL has caused some confusion in the field (Thomas, 2000). Current descriptions of PBL have the following salient features: (1) The project motivates learning and includes a culminating and “concrete” artifact (Helle et al., 2006); (2) PBL features a driving question that is student-centered and promotes sustained engagement toward the project development; (3) Engagement in the project is collaborative and demands authentic application (Blumenfeld et al., 1994); and, (4) The teacher scaffolds interactions between students and students’ cognitive processes and skills. Divergences in PBL across program approaches appear at the degree of integration of computer technology (Moursund, 1999), the degree of reliance on learning goals versus place-based authenticity (Blumenfeld et al., 1994; Lee and Miller, 2016), and level of individualization (Krajcik et al., 1998).

Much of the research on PBL focuses on the middle school and high school levels with a paucity of research in the elementary grades. The majority of the research that is available suggests a positive correlation between PBL and various student outcomes (Charara et al., 2021; Kokotsaki et al., 2016) and tangible benefits from PBL for student learning of content, motivation, or problem solving (Kokotsaki et al., 2016).

One study conducted by Harris and colleagues (2015), and using a randomized-controlled trial approach, indicates that sixth grade students who used materials designed with a PBL perspective outperformed students in the comparison curriculum on a robust outcome measure that was developed by the researchers aligned to ideas in the *Framework*. Specifically, the units aligned with several core science ideas and two science practices in the *Framework*—developing and using models and planning and conducting investigations. The results from the first-year implementation of a 2 year study demonstrated that project-based curriculum materials help students achieve specific inquiry learning outcomes when treatment teachers use materials and pacing guides with school support, including extensive professional development aligned to the materials.

Further results supporting PBL were reported in a high school math study by Boaler (2002), which did not employ random selection but matched schools for SES and race. It compared 300 matched students in one grade across three years in two schools, approximately half engaged either with the PBL approach while the other half had traditional instruction. The number of students in the PBL group who passed the national exam was three times that in the traditional group. The students in PBL reported less anxiety and exhibited increased facility with problem solving. Importantly, Boaler’s (2002) study suggests that PBL mitigates the effects of economic difference among students, whereas the traditional teaching approach exacerbated correlations between socioeconomic status and test results.

Historically, as a curriculum approach, PBL has had considerable purchase as being student-driven and individualized, with teachers enacting it in local contexts (Thomas, 2000). The localized design of PBL has promoted student choice and interest through deeply authentic questions, flexibility in process, and engagement in, and investment from, the local community (Larmer and Merendoller, 2010). In addition, individualized PBL experiences led to investment of teachers and students because of an opportunity to balance expertise on the part of the teacher while also drawing from students’ strengths, questions and skills. Studies also report that PBL enhanced teacher competency through soliciting and accessing available tools, community experts, and technology (Halvorsen et al., 2018; Miller and Berland, 2020).

Challenge presented by the Next Generation Science Standards

The Next Generation Science Standards (NGSS Lead States, 2013) are based on current research and their enactment is intended to scale throughout the United States. They describe sets of performance expectations for science understanding that students build

toward meetings by the end of each grade level or grade band across grades K-12. Based on the *Framework*, NGSS draw from research that very young students can engage in science practices, that practices are integral to developing understanding of science ideas, and that science proficiency builds over time with increasing sophistication (NRC, 1999, 2007, 2009, 2012). The *Framework* calls for learners to use disciplinary core ideas, scientific and engineering practices, and crosscutting concepts together to make sense of phenomena or solve problems—to engage in “three-dimensional science learning.” As such the *Framework* presents a vision that mirrors the conceptual work of science practitioners. The NGSS concretizes the *Framework*’s call for integrating different dimensions of science learning within three-dimensional performance expectations, envisioning what students should be able to do with knowledge and not just simply *know*. With developmental theory (NRC, 2007; Smith and Nadelson, 2017) and situated learning grounding its development (Bransford and Schwartz, 1999), the *Framework* and NGSS aim to address inequities in science learning experienced by underserved student populations in the US and provide more rigorous levels of teaching and learning of science understandings (Miller et al., 2015; Reigh and Miller, 2020).

Enactment of the three dimensions called for in the *Framework* and NGSS has presented a considerable challenge at the individual classroom level and at scale within districts. Proponents of the NGSS acknowledge a gap persists between what is promoted by the science research and policy community and what is taken up by teachers, school districts, and local communities (Duschl and Bybee, 2014). In practice, the implementation of the NGSS seems to require major investment in science teachers’ professional learning, an investment underfunded districts may not be able to make, or may be unable to prioritize.

Building on positions from *Taking Science to School* (NRC, 2007) and *How People Learn* (Bransford and Schwartz, 1999), the NGSS provide a tangible series of performance expectations that codify science learning as increasingly sophisticated demonstrations of science understanding where learners integrate disciplinary core ideas, seven conceptual understandings that cross disciplines, and eight science practices including argumentation, modeling, and mathematical and computational thinking. Unlike many state standards, which dictate the reproduction of isolated facts and ossified routines like the “scientific method,” the NGSS move away from discrete science ideas and memorization of steps to express what students should know and be able to do to meet performance expectations.

Merging the NGSS, with its focus on engaging all students across the US in three-dimensional science learning, with PBL and its focus on framing learning and engaging all learners with motivating and authentic contexts, we argue presents a powerful learning opportunity. Our goal is to productively merge these two approaches to support students in deeper learning, particularly at the elementary level where the need is great.

Research questions

In order to develop materials that use a PBL approach to engage students in three-dimensional learning, we ask.

1. How can we iteratively develop a comprehensive implementation system (i.e., teacher and student-facing materials, assessments, and professional learning) of PBL curriculum materials over three years of design cycles?
2. What would be a productive design approach to developing PBL materials that effectively address the NGSS?
3. What tangible characteristics would a final product feature that uses both PBL and the NGSS to promote student learning?

Methodology

We used design-based research (DBR; Barab and Squire, 2004) approach to iteratively design, develop, test and revise third and fourth grade PBL curriculum aligned with the vision of the *Framework* and the NGSS. Our Grade 3 work began with conducting exploratory teaching experiments with select teachers, moved to a pilot study of more refined materials with a larger group of teachers, a field study of polished materials with yet more teachers and multiple districts, and culminated in sharing the materials on an open-source online platform. The same development and revision cycle was used for the creation of fourth grade materials. In essence, we designed materials that could be implemented at a large scale to support all students in meeting the NGSS across entire districts, and we propose a more effective pedagogical model that combines the full scope of the NGSS with PBL. Using DBR, we have engaged in tweaking on-the-ground elements of this marriage to best address challenges with implementation creatively with iterative design.

Context

Multiple Literacies in Project-based Learning

The Multiple Literacies in Project-Based Learning (ML-PBL; Krajcik et al., 2015) project is a collaboration between Michigan State University and the University of Michigan. The intent of the project is to develop, test and iteratively refine Grades 3–5 project-based science curriculum materials aligned with the NGSS and PBL. To support students’ learning of science as envisioned in the NGSS, the design of PBL materials also focused on integrating additional literacies, primarily English language arts and math, and that also focused on cultural relevance, Social and Emotional Learning (SEL), and classroom discourse. Importantly, our approach goes beyond simply providing curriculum materials, and seeks instead to deeply attend to issues of implementation (Fishman et al., 2013; Penuel and Fishman, 2012). We seek to create a comprehensive implementation system where teachers are supported by

Table 1 Development and enactment cycle for third grade.

ongoing, sustainable forms of professional learning and have access to tailored three-dimensional assessments that can support enactment and instruction of ambitious PBL curriculum materials that support enactment of the NGSS.

Context of implementation

This ongoing study has taken place across multiple states in the US, involving more than 100 elementary teachers from 12 districts. (Insert information on teachers, students, districts in study).

Approach to design

The project has involved multiple cycles of curriculum development and revision. The study began with Grade 3 development in year one and began a new cycle of development for Grade 4 in years two and three. With each year, more teachers were added to the design project (See **Table 1**). Our first cycle of design and implementation culminated in what we refer to as *teaching experiments*. In this phase, we seek to observe the initial challenges the curriculum materials, professional development, and assessments present to a small cadre of teachers working closely with researchers, usually within one of two classrooms that cross districts. Data from the first phase is then used to inform the re-development of materials for a larger *pilot* phase of implementation in the second phase, involving significantly more teachers—in addition to working closely with a small cadre through teaching experiments—and where we begin to define larger problems of scaling across entire education systems. In an iterative fashion, data from the second phase is then fed into further refinements for use in *field experiments* in the third phase. Final refinement to our curricular materials, professional development and assessments are then made, and the materials are placed on Sprocket, an open-source, on-line medium, accessible across the globe.

Table 1 presents a summary of the cycles of development of the third-grade materials.

Employing design-based research methods

This project uses a framework that rests on the assertion that tenets of PBL and the NGSS can be productively woven together in materials to support enactment at large scales that shows integrity to PBL and motivates students to develop three-dimensional science understanding. We employed design-based research (DBR) methods to undergo iterative cycles of development to build

on theory of how learning occurs through the use of pedagogical and curriculum materials, professional learning, and assessment. This project reflects key characteristics of DBR: (1) a dual goal of developing pragmatic interventions for real-world use and the development of theory on how learning occurs through the use of the interventions, (2) iterative cycles in the research process, and (3) an appropriately robust approach to data collection on student learning (Wang and Hannafin, 2005). We created and revised materials in iterative cycles of design, implementation, as well as synergistically reviewed and examined opportunities for teacher professional learning. Importantly, we developed a set of design principles to support the implementation of these practices in the classroom (Miller et al., 2021b).

Barab and Squire (2004) suggest the use of DBR to examine the effects and promise of a learning design by applying instructional practices to real teaching contexts (Barab and Squire, 2004). Through the implementation of instructional practices, we seek to understand both students' learning processes and the impact of the designed intervention on student learning. DBR takes into account the underlying theory of the interventions, the features of the instructional activities or materials, and the contextual factors (Brown, 1992). Our theory within the ML-PBL project is that through thoughtful refinement of our PBL approach to incorporate the NGSS for learning and a coherent lesson-level design, we could develop a curriculum that has broad scalability as well as local potential to motivate and sustain learning for diverse contexts. In other words, we explored how to productively merge PBL features with principles of the NGSS. Teachers' understanding of the curriculum design approach used in ML-PBL and their capacity to implement these materials with integrity to designers' intentions was supported with recurring professional learning.

Logic model

Our overarching research questions explore how to support all students—particularly students from diverse backgrounds, including English language learners and students at-risk for underachieving or disengaging from science and school—in learning science through the design, development, and testing of PBL materials that integrate tenets of the NGSS.

The logic model (Fig. 1) shows how the features of PBL build from underlying theoretical ideas. To meet the challenges of diversity, universal design for learning is critical to provide differential scaffolds. We can accomplish this by providing various types of scaffolds and using the principles of universal design for learning—multiple representations, multiple means of expression and multiple means of engagement (Jimenez et al., 2007). Our PBL interventions have three major, complementary components:

Fig. 1 Logic model for ML-PBL design.

(1) PBL teaching and learning materials, (2) professional development, and (3) connections to community and family resources. These components, working together, should result in both classroom transformation and intermediate and distal outcomes. **Fig. 1** presents a visual of the logic model that explains how elementary students' develop increased engagement and performances in science.

Data collection

According to [Cobb et al. \(2003\)](#), "*design experiments create the conditions for developing theories yet must place these theories in harm's way*" (p.10). We expected to observe the need to readjust the union of PBL and NGSS as our project unfolded through the collection of (1) field notes of ethnographic close classroom observations, (2) interviews of students and teachers, and (3). Collection of artifacts and assessments from the classrooms.

Studying implementation of materials

In the first 3 years of the research study, we collected careful and detailed field notes from multiple school sites within districts in the Midwest US. For the research reported in this manuscript, data was collected in schools where the team developed field notes and collected video data one to three times a week (~40 min) across classrooms. Our protocol for studying classroom enactment includes an in-person observation by an observer who is familiar with the intent and flow of the unit, and has learned to look for the features of PBL that frame the lessons using an Observation Tool designed specifically for the ML-PBL project. Using the tool, we scored teacher enactment of specified components of the lesson, as well as various features that are consistent with PBL, such as use of the driving question, engaging students in figuring out, and sense making, discourse, and development of artifacts.

The focus of the collection used a wide lens to capture whole class implementation of the teacher and whole group discussion in order to broadly ascertain fidelity to the curriculum as well as a more narrow lens employing interviews and following specific students over time. During unit implementation in the second-year pilot and third year field tests, we conducted classroom observations of each teacher at least once. We averaged three to five observations per teacher per unit.

The research team met regularly to compare field notes, and observations of lesson enactment, and professional learning enactment. Questions the team asked during this phase included, "Does the design of PBL and NGSS work to promote engagement and learning?" "What are the processes for student learning, including socio-cognitive aspects?" "How can we improve opportunities for students to engage in the NGSS practices and use their science learning in projects?" "What challenges do teachers experience in enacting the curriculum?"

We found that the most profound outcomes were formulated after the first and second years of the enactments. As we concluded the first round of completion of the units, our work revolved around the design work of ML-PBL units: (1) organizing learning to build coherently over time, (2). Organize learning to culminate in artifacts, and (3). Support shifts in teacher practices through use of assessment, supportive features, and professional learning. During each cycle, we integrated on development of units and continued to inform a final system of assessment. In the final cycle, we focused most intently on professional learning that emphasizes integrative design. Together curriculum, assessment and professional learning worked as a system that would be tested and redesigned to derive increasingly scalable and sustainable materials.

Data analysis

To analyze field notes and observations, we followed a systematic data analysis process modified from [Strauss et al. \(1996\)](#).

Step 1: Researchers read through fieldnotes and observation data several times to create tentative proposed themes that were emphasized or repeated by a teacher. We developed themes related to the challenges and opportunities related to features of PBL and the three dimensions of the NGSS, adding more themes in subsequent reads (i.e., student voice, adaptation of feature, community involvement). We used the following questions to search for tentative themes of challenges and opportunities for design and revision:

1. How do features of PBL align with meaningful learning of the NGSS?
2. How can we describe challenges that the features of PBL present for teacher enactment?
3. How does professional learning support teachers in enacting the materials to use PBL for meaningful three-dimensional learning?
4. How are scaffolds in the materials taken up to support PBL for deep learning of the NGSS?

Across teachers and sites, we sought patterns indexing themes related to these questions. We discussed, took extensive meeting notes, and wrote summaries of these themes across teachers, highlighting specific responses to our four questions. The proposed themes were tentative themes that emerged from analyzing the data sources. After this initial analysis, we would address an opportunity or challenge identified in the classrooms by adjusting the curricular intervention (e.g., teachers adding to the lesson, adapting for students with IEPs, skipping lessons, or parts of lessons), gather more data, and follow the same processes looking for new proposed themes or evidence to support a previously proposed theme. In each step, we returned to our theory of PBL (i.e., meaningful and engaging question contexts, and useable supportive design for teachers) and theory underlying the NGSS (i.e., coherent, rigorous, and evidence-based learning progressions) and its enactment.

- Step 2: Across units, we continued to analyze additional data as we collected it, and as we introduced new designs. Seeking to further refine themes, we looked for evidence to support themes informing iterations that address challenges and opportunities.
- Step 3: In Step 3, we focused on responses to iterations. We sought additional support for the themes of challenges and opportunities of the NGSS and PBL by reviewing recent data to find possible evidence of responses to iterations.
- Step 4: In Step 4, we searched for patterns and shifts in the themes to create an overall summary of the themes that occurred across the year. In this stage we summarized solutions to challenges, and critically analyzed the four questions to inform further revision of the design. We again kept focal theories of PBL and those informing the NGSS (i.e., three-dimensional learning) and examined theory for scaling. This step completed a cycle.

Design cycles

For development, we engaged in multiple design cycles (Brown, 1992; Collins et al., 2004; Sandoval, 2014). Here we report on three of our yearly design cycles (See Table 1), reporting on the design cycles that occurred from school years spanning 2015 through January 2018. Each cycle included design, development, enactment, critical review and analysis of collected data, and revision of the curricular tools (Barab et al., 2007), implementation structures (Penuel et al., 2011), and professional learning environment design (Rosebery et al., 2016). Cycles were ongoing from September to August of each school year and culminated with new broader and revised theoretical principles as well as refined and further developed curriculum materials, professional learning strategies and assessments in the late summer of each school year (Fig. 2).

Iterative cycles of design, testing, and revising

During the first design cycle, we collected and analyzed field notes and observation notes. In the second cycle, we created assessments, or performance tasks and revised the curricular format based on the review of the data, and again conducted ethnographic and interview data collection. In the third cycle, more revisions were made leading to the development of the final curriculum and the design of professional learning supports based on current theoretical principles. We will reflect on the need for more changes as the current design cycle comes to a close.

First cycle teaching experiments

Design

Extensive planning and preparation in the first cycle provided overarching plans for unit development, including anchoring phenomena of units, assignment of standards to be addressed, development of lesson-level learning goals or Learning Performance statements (LPs), as well as unit and lesson templates. In this cycle of design, we solidified and instantiated principles for incorporating English language arts, mathematics, cultural relevance, SEL, and classroom discourse.

The process of resource design and development reinforced design team members' understanding that the development of rich PBL resources to support 3-D learning and meet the NGSS and other interrelated goals (e.g., SEL) required a purposeful collaborative and iterative process. Design team members collaborated on developing and revising evidence statements, SEL learning objectives, and cultural relevance and discourse objectives, making these explicit and a central part of the lesson design and unit progressions. Identifying stages and responsibilities within the iterative process, and continually revising plans based on desired versus actual experiences and outcomes and balancing the need for rigorous learning goals with providing adequate supports to help students meet them, provided extensive opportunities for rich inter-team discussion and for thinking of ways to identify, organize, prioritize, and eventually streamline steps in the process.

The team worked to maintain focus on the goals of PBL and 3-dimensional learning from the NGSS. Weaving together PBL and 3-dimensional learning offered a new vision for classrooms in which all children, regardless of their backgrounds, experience rigorous learning that pushes their thinking forward, so they have the intellectual resources to develop agency in science and in making sense of the world in which they live. At times, because of time and capacity pressures and differences in our experiences within the educational system we regressed into traditional approaches and lenses in the curriculum and theoretical framing. The

Fig. 2 Foci of design cycles.

need to continually recommit to an innovative perspective—and break away from traditional approaches—is a tension that all designers face. To push the field forward and learn what is possible, we needed to stay true to the premises of PBL and NGSS, keep our learning goals rigorous, and believe in what is possible, not what is expected.

Testing and analysis

In the first cycle, we developed and implemented the first curriculum design and associated professional learning opportunities. Teaching experiments using unit resources occurred with a small cohort of teachers in multiple schools. As teachers received professional development on using the draft resources in teaching experiments, researchers engaged in the iterative process inherent in the development of PBL curriculum resources. Purposeful iterative planning, and retrospective analysis of observations and field notes identified needs that served as foci within the development process.

In the testing and analysis phase, we were cognizant of the importance of interdisciplinary teams: The various team members—researchers and practitioners with expertise spanning science education, math and language literacies, and SEL among other areas—brought different strengths and perspectives to the project work. This assemblage of expertise enhanced the materials and what could be accomplished.

The testing, analysis, and revision work proved extremely iterative in nature. Throughout the process, the learning goals for lessons (i.e., 3-dimensional learning in science, social emotional, and discourse aims) remained at the forefront. Unit-level learning goals (expressed as performance-based evidence statements) were expected to frame the vision of each unit. Our work made use of data from the small cohort of teachers enacting the lessons to drive revisions of lessons and the revisions of progressions and scaffolds. As the team collected a first round of rich data from the first implementation, we needed to elaborate a set of collaborative practices around the revision process, expressed as a set of shared design principles. We designed and redesigned prior and subsequent units using these design principles, leading to student materials used in the second cycle.

Outcomes and reflections from the first design cycle

Major lessons learned with respect to the design principles from the first cycle included the following:

- (1) **Units needed to better attend to issues of coherence:** The simultaneous development and redesign of units, and rapid development of additional units challenged the team to create tight connections between and across units with respect to promoting coherence, where learning becomes progressively more sophisticated within the year and across years (Fortus and Krajcik, 2012). Specifically, the team experienced challenges in developing lesson-level learning objectives (i.e., learning performances) that increased in sophistication over time and pushed students to develop a deeper understanding of disciplinary core ideas while increasing their engagement with practices, and furthering their capacity for productive discourse and opportunities for SEL. The group confronted this tension, moving forward, to be resolved in subsequent cycles.
- (2) **Current level of scaffolding proved insufficient:** This item is related to staying focused on PBL and 3-dimensional learning. The group needed to design materials to support students to take part in classroom tasks that require planning, synthesizing, sensemaking and using ideas to understand their world. All students can take part in these synthesizing and integrating tasks. Our challenge was to develop and include the structures and scaffolds to support rich academic practices in which all learners can productively and collaboratively engage. Finding the right level of scaffolding that supported learners in meeting the multifaceted aims of lessons (i.e., 3-dimensional learning, SEL, discourse) without overcomplicating lessons and diminishing their usability required attention in the revision process.
- (3) **Designing supportive features for teachers:** Providing the right level of support for teachers was a challenge for design. One of our goals was to provide highly specified development materials for students and teachers. However, too much support (as text in the lessons), created situations where teachers did not read the materials. Conversely, there was a danger of providing too little support. The team returned to this tension repeatedly. We tried providing links to supports from a lean document that provided a more succinct overview of lesson structure. In addition, taking an asset-based approach to teacher support, which aligns to evidence that teachers will develop skills in a just in time-based fashion (Miller and Shelton, 2021), meant taking into account the reciprocal nature of practices, goals and supports and context (including community), and how they work together to enhance teacher practice and reflection on practice.

Second cycle pilot studies

In the second cycle, the ML-PBL Team focused on completing teaching experiments with Grade 3 units, reviewing and revising Grade 3 units, and designing and developing initial drafts of Grade 4 unit resources. Year 2 early teaching experiments with Grade 4, and pilots of Grade 3 took place in seven schools. The team continued to design to address issues of coherence identified in the previous cycle, as well as teacher and student support for teaching and learning. This cycle was laser-focused on supporting teachers by providing a variety of assessment supports. Teachers could address how they were supporting student learning and reflect on their own teaching practices through multiple informal, formative, and summative assessments.

Design

This cycle saw enhancements in our design-based research process for unit development, particularly as it relates to assessment and evidence of 3-dimensional learning. Although the process was iterative, the design process began by developing learning goals—specifically, lesson-level 3-dimensional Learning Performances—aligned to PEs. These learning goals were enhanced and revised throughout unit development and subsequent iterating in response to ongoing data collection.

Testing and analysis

The development team made several adjustments and additions to the testing and analysis process. Development and revision of design for materials resulted from feedback from teachers during professional learning sessions and from talking with teachers during the enactments, review of videos taken during the first-year enactments, field notes taken during the enactments, and review and feedback regarding the units given by project team members. We were interested in how teachers were using the formative assessments for understanding goals of the lessons and planned to revise assessments based on feedback in the third cycle. We found the feedback provided by the teachers extremely valuable in revising the units and lessons and reexamination of documents.

Outcomes and reflections from the second design cycle

Unit Development revisions. An important modification made to the units in this cycle was using a theme that cuts through each of the units. For example, because energy and energy transfer is an important disciplinary core idea and crosscutting concept, we decided that each of the fourth grade units would build and reinforce this important idea. We also more systematically focused our efforts on making the units more interdisciplinary. This can be seen, for instance, in the first fourth Grade unit, *What causes the land in our community and world to be shaped in different ways?* In this unit, we focus on students using and revising their developing understanding of energy and energy transfer to figure out how water and wind change the earth. Another revision was to make explicit how we engage children in the engineering design process and in various design elements throughout all of the units. We focused on integrating engineering, so children have opportunities to engage in design processes. Our revision process also involved focusing more explicitly on discourse, equity, and SEL. Our goal was to include discourse prompts and “look fors” (i.e., tangibles that teachers can look for to see if students are engaging in the lesson as intended) in every lesson and either an SEL or equity lesson in each learning set.

Assessment Development. During the second design cycle, team members collaborated on refining design principles as well as designing and revising components of an assessment system, including: (a) formative and summative assessments based on learning performance statements, (b) discourse objectives, (c) formative assessment, “look fors,” and (d) evidence statements, all integrated in lesson design and unit progressions. We also developed a plan for an end-of-year series of assessment tasks to be used during field testing in Year 3.

The ML-PBL project aimed to provide meaningful and actionable information about the progress and capacities of individual students and groups of students toward meeting learning goals, as well as students’ ability to demonstrate and apply understandings in new contexts. Assessments informed teachers’ instructional practices and interactions with students and for describing a bigger portrait of student learning. As designers, we found the assessments valuable in providing information with respect to the design of units.

To accomplish these aims, the assessment strategy included specification of learning performances (LPs; the lesson-level 3-dimensional learning goals), as well as end-of-unit learning goals (which students’ progress toward served as evidence to make “claims” of students’ enduring understanding). This variety of performance learning goals necessitated multiple types of performance-based, student-generated artifacts. Adherence to the project-based context helped to ensure coherence among artifacts. Throughout each unit, learning goals and corresponding artifacts build on each other and offer opportunities for students to reflect on and revise science understandings and practices.

Formative assessment opportunities within each unit continuously gather evidence about student learning. Assessments included a variety of strategies—including teacher observation of student interactions and work (“look fors”), planned-for interactions, and curriculum-embedded assessments—all designed to support teachers in identifying each student’s place along a progression of learning, provide feedback, guide plans for adjusting instruction and providing scaffolds, and for developing students’ self-regulation strategies.

Units also include end-of-unit culminating artifacts that provide tangible means for students to demonstrate their ability to connect learning experiences in response to the unit driving question. A performance-based assessment at the end of each unit provides an opportunity for students to extend and apply what they learned in a related, new context, as evidence of enduring understanding.

Along with culminating artifacts, to help triangulate whether students have developed the enduring understanding goals of the unit, our assessment system includes Unit-Specific Pre- and Post- Assessments of Enduring Understanding in which students utilize disciplinary core ideas, science and engineering practices, and crosscutting concepts while interpreting text and images and determining evidence to support two claims (i.e., generalizations abstracted from the enduring understanding).

The ML-PBL team also developed a series of summative assessment performance tasks (3–4 tasks) to assess student learning. These 3-dimensional tasks are administered at the end of the year, assess the scope of grade-level PEs, employ contexts other than those used in ML-PBL units, and provide a means of comparing the performance of students in ML-PBL classrooms with those from non-ML-PBL classrooms.

Third cycle field experiments

The third cycle continued to provide rich data to support the redesign of the units and the assessments. During this cycle, we focused on revision, including the testing and analysis of Professional Learning materials. We applied an iterative process informed by design-based research to develop and redesign professional learning experiences, which proved key to supporting enactment with higher fidelity to our design principles. We gathered and analyzed data from enactment surveys and observations, whole group reflection during professional learning sessions, and teacher interviews to modify and improve professional learning for teachers.

Design

With each new cycle we enhanced our support for teacher sensemaking about PBL practices. During this cycle we incorporated small-group and whole-group discussion prompts that engaged the teachers in engaging in argumentation about teaching and learning within the units. We developed a Professional Learning Framework that facilitated sensemaking about lesson design, and strategically involved our returning teachers.

The professional learning framework focused on the following: (1) Targeting experiences of one (or more) key lesson(s) in each learning set that engage teachers in sensemaking about how to support students in the “figuring out” processes that occur throughout the unit to move toward the final artifact and building proficiency in meeting bundles of PEs; (2) Soliciting teacher-driven discussions on the affordances of the features of ML-PBL lesson design; (3) Fostering conversation among returning and new ML-PBL teachers about enacting PBL; (4) Highlighting the coherence across learning performances; and (5) Using video of classroom discussion, artifacts, questions, and examples of student work to support teachers in critically reflecting on the ways that PBL supports equity, engagement, and community building.

Further design for professional learning focused on coherence across experiences. Each professional learning opportunity built on earlier opportunities, deepening the teacher-facing professional learning DQ (How can we support students in sensemaking in PBL?), artifacts, and engagement with the lesson features. Although the Professional Learning structural framework remained the same, the Professional Learning outcomes were designed to build one upon the other. We began the face-to-face Professional Learning by recording some of the key take-aways of the last unit, including use of crosscutting concepts, science and engineering practices, and disciplinary core ideas. Then we asked and recorded what the take-away would look like if students had made greater gains.

Each video conference meeting focused the teachers to collaboratively reflect on the feature(s) of the student-facing materials with respect to the lesson-level 3-dimensional learning performances. They discussed the alignment of the feature with the learning performance, and the evidence statement. They were tasked to work together to describe how the lesson feature provides direction for the informal and formal assessment. In the face-to-face Professional Learning experiences, we repeatedly returned to the lesson structures. We analyzed how the discourse supports were used by the presenter with teachers, how the learning performance was met in the lesson, or how the evidence statement is instantiated in the artifact. We returned to the unit Driving Question and three-dimensional learning performances of student-facing materials to support teachers in explaining the intentionality of each learning set, how learning sets build on one another, and how coherence is met.

Testing and analysis

In this cycle, we solicited teacher-driven discussions about the affordances of the features of the current iteration of the ML-PBL lesson design. One aim for the professional learning was to provide support for how teachers can use and interpret the lesson structure. Based on teacher feedback, our lesson structure was initially viewed as “lengthy” and difficult to navigate. However, we saw consistent evidence (as confirmed through classroom observations) that the lesson format promotes 3-dimensional teaching in PBL when teachers engaged with provided supports: teachers enacted lessons efficiently with positive results.

During interviews, teachers described that they appreciated the new professional learning design. Multiple teachers have expressed that they now understand the whole picture of each unit and know how the learning progresses, indicating a deeper grasp of the coherence intended within and across units. They found the professional learning “interesting” and “purposeful” and explained (during interviews) the “purpose of each learning set and how 3D learning develops throughout the unit.”

Analysis of the revised design of the video conferences and face-to-face professional learning experiences by the ML-PBL team drove sensemaking about the relationship between lesson structure and features and enhanced three-dimensional instruction. The third cycle of design focused on increasing awareness of the need for changes in practice on the part of the teacher. The video conference discussions from professional learning sessions were analyzed, providing more strategic guidance on what proved productive for teachers’ learning. For example, when the PL facilitator encouraged examination of classroom practice for meeting the 3-D learning performance and/or identified how that practice hindered or supported student learning, agency, and SEL, this proved a high-leverage move within the professional learning series.

Our iterative design of the professional learning opportunities focused on how teachers’ learning progressed, and highlighted changes in students’ practice as evidence of learning and growth in PBL and the NGSS. For example:

- After completing the first third grade unit, teachers stated that their students had started to listen to their peers’ ideas in small group discussions. They agreed that the students would need to work next on building students’ capacity to listen and productively use peers’ ideas.

- After the second third grade unit, the teachers agreed that their students had created models featuring cause and effect. They thought that the next step would be to model interactive relationships where one component is changing. (This is a goal for practice in the third unit, Birds.)
- Using this design change, some teachers reported that they saw themselves as agents in sensemaking about Teacher Practice Knowledge. This change indicates the professional learning promoted (1) enhanced reflective practice on the part of the teaching community, and (2) more thoughtful engagement with the educative features of units.

Notably, rubrics developed for key formative assessment opportunities supported teachers in providing students with timely feedback to guide their next steps in learning. Assessment data from this cycle will be analyzed to provide evidence of resource effectiveness and future design directions.

Outcomes and reflections toward fourth cycle

The new professional learning design was intended to emphasize teacher sensemaking about the progression of students' learning as well as the purpose of the DQ and the final artifact in the units. The professional learning highlighted the features of PBL by having the format teachers' experience employ key features of PBL, including a teaching-focused Driving Question (i.e., How can we support students in sensemaking in PBL?) and a culminating artifact. The final artifact for professional learning was to develop a model of the progression of students' 3-dimensional learning. Coherence, being a key feature of PBL and the NGSS, also featured prominently in professional learning. We see our role as facilitators to support teachers in employing PBL practices effectively through intentional reflection of evidence of what is happening in their classroom (i.e., engagement, informal assessments, and "look fors") and continued engagement with how lesson-level learning performances coherently build into unit-level performances (enduring understandings and unit-based and summative assessments).

Lesson-level features (i.e., learning performances, figuring out statements, "look fors", evidence statements) guided teachers in 3-dimensional instruction where students actually use disciplinary core ideas, science and engineering practices, and crosscutting concepts to make sense of the world. Lesson-level features supported teachers in conducting formative assessments throughout each unit. For most teachers, 3-dimensional instruction represents a major change in practice. With its focus on teachers understanding three-dimensional learning performances, our professional learning design in tandem with associated curricular materials provided robust support for helping teachers move toward 3-dimensional instruction. Evidence we have collected to date indicates that teachers use lesson-level features with increasing sophistication over time.

From the outset of the ML-PBL Project, our team has taken steps to more clearly articulate the vision of the *Framework* and the NGSS—engaging students in using multiple science and engineering practices, disciplinary core ideas, and crosscutting concepts as tools to make sense of complex phenomena. We have designed units of instruction that provide a coherent progression of rich opportunities for students to develop sophistication in each of the three dimensions of science proficiency—opportunities for filling a toolbox with practices, ideas, and conceptual tools that can be used to explain phenomena and solve problems relevant to learners.

In terms of assessment, our continued goal is to support teachers in supporting students to access this toolbox of ideas, ways of knowing, and negotiate, reorder, or otherwise revise these resources for immediate use in an assessment environment. We strive to design assessment tasks that will allow students to consider how to use multiple scientific practices, and various elements of disciplinary core ideas and crosscutting concepts to explain phenomena or solve problems presented. We believe that assessing in this manner will promote a deeper understanding on the part of students and teachers of what it means to "do science" and provide opportunities for students to develop persistence and employ creativity in science.

Discussion

This multi-cycle design-based research project offers a promising example of how 3-dimensional project-based learning units, when tightly coordinated with assessments and professional learning in a comprehensive implementation system, can provide rich learning opportunities that productively blend elements of PBL with those of the *Framework* and NGSS, namely 3-dimensional learning. We began with an initial understanding of PBL that consolidated and expanded the features of PBL in the literature, based primarily on PBL science research at the middle school (Blumenfeld et al., 1991). We showed that PBL environments, when thoughtfully integrating elements of the NGSS, can support instruction that is well-scoped and coherent, and implementable at large scales. This work also points to how the three-dimensional learning of the NGSS provides a vehicle for not only important correlated goals (e.g., SEL, discourse), but can support the joining together of learning as a participatory performance in a community with using science to explain phenomena and solve problems. Tangibly, we extended and modified the 6 features of PBL to include the NGSS (in italics) below.

1. They start with a *driving question about a phenomenon to be explained or an engineering problem* to be solved. The NGSS adds parameters to the scope and nature of the Driving Question in PBL, specifically addressing the nature of the question at hand, and infusing the disciplinary context.
2. They focus on *3-dimensional learning goals* that align with key NGSS science standards and frame demonstration of student mastery on assessments.

3. They require *participation in NGSS scientific practices as described by the Framework and NGSS*—processes of problem solving that are central to expert performance in the discipline *and the integration of literacy as tools to support students in sensemaking*.
4. As students explore the driving question, they engage in *collaborative sensemaking activities* to build shared knowledge—the solutions to the driving question.
5. While engaged in the *practices of science*, students are *scaffolded with tools* that help them participate in activities considered beyond their ability.
6. Over time, students iteratively *create a set of tangible products* that address the driving question using *science and/or engineering with increasing sophistication*. These are shared artifacts with local impact, publicly accessible external representations of the class's learning.

The NGSS specify the learning goals as three-dimensional and as collaborative participatory practices. In this way, the NGSS condense features 2, 3, and 4. Students must show mastery through engaging in the practices, which cannot be developed in non-collaborative contexts. This condensing also offers new conundrums about assessment, which we also address in the project.

Driving Questions. This work highlights how driving questions can serve as an integration point for PBL and the NGSS. We found **driving questions** needed to be meaningful and focus on a phenomenon or problem at the unit level. For example, “How can I help the birds in my community, so they grow up and thrive?” These driving questions were meant to motivate the students, be answerable with different levels of sophistication over five weeks and leverage a bundle of NGSS Performance Expectations. This driving question encompassed a phenomenon that required understanding of life cycles, genetics, behavioral characteristics, and climate and weather. The questions highlighted the need to use crosscutting concepts—patterns, scale, stability and change, and cause and effect, and use all of the practices, including developing models, constructing explanations and designing solutions. For example, in the bird unit, the students need to figure out where their bird might be in its life cycle and how many were sighted locally. They used this information to consider what sort of food, and what quantity, the bird might need.

3-Dimensional Performance-based learning goals and Collaborative Practices. We use **3-dimensional learning performances (LPs)** for each learning set and lesson in the learning set, which act as learning goals at a smaller grain size using the same 3-dimensional structure of performance expectations. A learning set is a coherent set of lessons that build to answer a sub-driving question necessary to answer the driving question of the unit. For each unit, we have roughly 25 learning performances. Since the learning sets were related, the LPs often changed as the idea deepened or the practices changed. The LPs in each learning set, a coherent set of lessons that build to answer a sub-question, focused on addressing different aspects of the same element of the disciplinary core idea. We provided an organization showing how each lesson-level learning performance aligned with an evidence statement that clearly explained what data the teacher would observe as evidence that the three dimensions of the learning performance were met by students. In a unit, the learning performances encapsulated all of the dimensions in the PE bundle, usually about 4–5 cross-disciplinary PEs. To complete the project, the LPs in one unit called for all of the NGSS science and engineering practices and several crosscutting concepts. All of the project work was collaborative for the students and required the students to use sensemaking to exchange and creatively build on one another's ideas. In our units, the practices were incorporated into the learning performances, and they were enacted by the entire class at the same time, with direction and support from the teacher.

Artifacts. This work showcased how our team conceptualized the culminating artifacts in PBL in relation to the NGSS. We began our work with a theoretical design for artifacts that reflected the coherent building of knowledge over time intended in the units, directly related to answering the driving questions, and aligned with focal science and engineering practices. Notably, artifacts were also meant to remove barriers between the school and the community with a presentation of new understanding with a tangible artifact.

Discourse Moves. This work highlighted the central role of discourse moves to integrate PBL and NGSS. Developed by the Wisconsin Center for Educational Research (WIDA), our discourse moves were purposefully integrated into units and their use was made explicit to teachers in professional learning and in the lesson plans developed. The discourse moves respond to the call in the English Language Proficiency Development (ELPD) Framework for supporting the Language of doing science (van Lier, 2006; MacDonald et al., 2014). Our approach shows the tight integration of elements with one another, including discourse with SEL practices. The Discourse moves support all of the purposes for engaging in a practice through discourse.

For example, after a student expresses an idea while engaging in modeling, the move, “help clarify an idea” means that the teacher would ask questions seeking to make the language more specific and clarify the idea; and so both linguistic and cognitive demand would be supported—and the purposes of expressing the idea are accomplished.

Equity Goals and SEL Goals. We also showed how our approach productively addresses SEL as an essential correlated goal that supports the integration of ideas from PBL and NGSS. Our first design included Equity and SEL goals. In this iteration, we developed these goals where they made sense in terms of the narrative of the unit (i.e., we did not create SEL lessons for the sake of “covering” SEL). For example, the SEL goal is the following: “Identity development during challenges: We can learn to be comfortable with uncertainty and take on the challenge of collaborating with others and new ways of engaging with content.” In our first design, this goal was written as a corroborating learning goal that manifested as the student participated in the activity.

Through the curriculum, we promoted the view that SEL builds from opportunities within PBL, but at the same time, that it is an essential component for success in PBL. The co-development of SEL and 3-dimensional learning was intended to form a self-sustaining system that fosters an environment of strategic reasoning, self-monitoring and reflection, risk taking, collaborative skills, and problem solving. In other words, we hold that the development of SEL and 3-dimensional learning must be reciprocally supported to achieve success in project-based learning.

Assessment Design and Approach. Lastly, we specified an assessment framework that articulates how learning performances (lesson-level learning goals) can serve as a practical means to describe how students are making coherent (i.e., building over time) progress toward the end-of-unit or end-of-year NGSS performance expectations. In addition, we showed how we can support teachers' use of learning performances through tangible supports like evidence statements that describe what students must say/doing to demonstrate proficiency.

Conclusion

The *Framework for K-12 Science Education* and the subsequent NGSS present a new vision for science teaching learning. The *Framework's* vision is for all learners throughout the United States to develop the intellectual tools, creativity and personal disposition so that they can make sense of phenomena and solve problems that will make a difference in their lives or the lives of members of their community. But for the vision of the *Framework and NGSS* to be realized, school districts and teachers will need curriculum materials, assessments and professional learning that embody that vision—they will need a coordinated comprehensive implementation system. PBL with its focus on students finding solutions or building understandings in a collaborative manner represents a promising approach to use with the NGSS. As our research shows through several cycles of enactments, however, modifications to the design features of PBL need to be made to properly address challenging learning goals aligned to the NGSS and ensure the engagement of learners.

Our design-based research project that we have conducted over multiple cycles has focused our redesign on several key features of PBL. We encourage other researchers and designers to engage with these features and test their efficacy in further settings.

- Professional learning and community building that puts teachers in the role of “figuring out” that students need to grapple with making sense of complex and compelling phenomena or meaningful problems and that such efforts take time. Learners build knowledge that they can use over time as they grapple with situations that are important to them.
- Materials need to focus on supporting teachers' understanding of what the learning goal is and how the artifact helps learners build that understanding as well as social emotional goals of sticking to tasks.
- Scaffolds, including various forms of embedded assessment, need to focus on using student ideas as conceptual tools to further make sense of phenomena or design solutions to problems. In such an approach, not only will students' science proficiencies increase over time, but how they orient toward science will change as well.

The ML-PBL project focuses on integrating the vision of student engagement of PBL environments to support the 3-dimensional learning vision of the *Framework and NGSS*. Although the coordination of materials for teachers and students, professional learning and assessments show promise in promoting learning and social emotional outcomes, more work needs to be done, particularly around how to maintain such a capacity for supporting teachers' implementation over time.

Project-based learning that merges with the vision of 3-dimensional learning from the NGSS promises to promote increased engagement and learning. The work reported in this paper provides insights for how to iteratively design teacher and student project-based materials to focus on students meeting learning goals yet maintain a high level of student cognitive engagement. More broadly, this work presents one approach, a promising avenue where a comprehensive implementation system supports a generation of learners to build their capacity to work together to innovate together, and to solve the complex problems of our times.

Introductory words

Nêhiyaw and Saulteaux scholar Margaret Kovach (2009) states, “we know what we know from where we stand” (p. 7). We stand on, live with, and learn from the traditional lands of the Indigenous peoples of Musqueam, Squamish and Tsleil-Waututh Nations (Nicol, Vancouver, Canada), Songhees, Esquimalt and WSÁNEĆ Nations (Thom, Victoria, Canada), and Cree, Blackfoot, Dene, Métis, Nakota Sioux, Iroquois, and Saulteaux/Ojibway/Anishinaabe Nations (Glanfield, Edmonton, Canada). As we write this paper, we welcome the recent rains that suppress nearby forest fires both to our south and within our provinces. The rains, clearing air of ash and haze, nourish thirsty great cedar trees as salmon make their return from the Pacific Ocean to where their journey begins in the streams and rivers, high in the Canadian Rocky Mountain headwaters.

We open this paper by acknowledging our relationship to and with land and the ways these lands, where we live and work, nourish us in multiple ways. We use place/land in these introductory words to recognize these lands as the territories of the First Nations. Through this acknowledgment, and our subsequent writing, we invite you into Cree scholar Willie Ermine's (2007) notion of an ethical space, a space that grows when different positions, worldviews, philosophies, and intentions meet, confront, and engage with each other. We recognize that different worldviews frame how place and land are conceptualized in the literature. In this paper we use place and land interchangeably.

In the next sections we consider how STEM integration is typically conceived and the ways such perspectives frame relationships between humans and land/place. What results is a view of STEM (science, technology, engineering, and mathematics in K-12 and higher education) discourses as not currently connected *with* place. More specifically, we observe and experience STEM as positioned *on* land and that which *uses* land as a resource to be manipulated for human-centred economic desires. Through this writing, we work to open an ethical space in which to explore how Indigenous and ecological worldviews can enable understanding humans and more-than-humans as connected *with* place and *as* place, and in turn, occasion radically different perspectives and possibilities for STEM.

STEM as integration

Growing international interest in STEM integration focuses on the respective disciplines providing interdisciplinary settings for engagement (e.g., National Science and Technological Council, 2018; Parkin, 2018). For many, such as the UK Royal Academy of Engineers, STEM integration grounded in engineering principles supports students in “thinking like an engineer” in order to “develop more and better engineers” and to meet the growing economic demand of STEM skills (Lucas et al., 2014, p. 1). Research in this area demonstrates how even young students build disciplinary knowledge through engineering and modeling processes by

designing earthquake resistant buildings (English et al., 2017), building and modeling bridges (English, 2017), creating periscope optical instruments (King and English, 2016), and designing gears (Deis and Julius, 2017) including windmills and circuits (Wendell et al., 2017). Studies and calls for STEM integration tend to focus on developing and applying STEM disciplinary knowledge and skills. Less common but increasing are examples and calls for STEM education that critically question cultural values and environmental implications of STEM activities, such as: Whose interests (human and more-than-human) do these STEM activities serve? How do these particular STEM activities create benefits for some and barriers for others including individuals, communities, corporations, and living systems?

In the area of mathematics education Richard Barwell (2018), drawing upon mathematics educator Skovsmose (1994) approach to critical mathematics education, responds to the global climate change challenges by examining how mathematics can format our actions and influence “what we experience and how we act” (Barwell, 2018, p. 152). In the case of the current pandemic, mathematics or STEM formats how we act and interact with each other in terms of government recommendations (or requirements depending on where you live) for 2 m physical distancing and the wearing of masks, along with restrictions in mobility, employment, business operations, and receipt of economic stimulus plans. Our human or societal response to the pandemic is formatted by the predictions of mathematical models and machine learning algorithms. And, just as Barwell notes in referencing climate change, it is our response to the crisis that changes the structure of society through implementing (or not) various policies, laws and practices. The global response to COVID-19 is changing how we, as humans, interact with each other, how we treat each other, and how we interact within the world we live as human and more-than-human worlds (Abram, 1996).

Turning to river, story, and Indigenous thought

In British Columbia (BC), glaciers shape river headwaters into mountains and valleys running north to south. Here the Columbia River begins its journey in Canada’s Rocky Mountains, draining the snow melt from high mountains and interior rainforests through flowing streams and tributaries (see Fig. 1). As it flows, the river constructs a pathway, carrying minerals from mountains to the lower valleys, tumbling boulders like pebbles while cleaning the gravel bed, transporting nutrients to the flood plains, and washing fallen trees clearing debris along the banks. An international boundary cuts through the basin’s natural landscape—rivers and mountains sliced and severed by an invisible border that divides the river’s geography. South of the boundary the river flows through glacial-formed flood plateaus before twisting and turning to meet the Pacific Ocean. As a life force, a source of energy and power, the river once welcomed tens of millions of salmon at its mouth for their annual swim 2000 km upstream and hundreds of kilometers inland to spawn in the upper basin. For thousands of years the river has fed many: salmon and trout, grizzly and black bears, eagles and herons, sea lions and great killer whales, old growth forests, mosses, and wetlands, as well as Indigenous peoples and later settler colonizers.

Since the late 1800s the river has served as a resource for human use; a source of trade currency, and something to be controlled. Flowing through mountain gorges to great plateaus meant the river’s water levels fluctuate throughout the year, flooding properties and towns. Humans had the mind-set and tools through science, technology, engineering and mathematics (STEM), to construct massive dams along the river. And while dams offered solutions to managing the river’s unpredictable floods and producing electric power, these solutions also created problems, including severe destruction of the river’s spawning ocean salmon. In response, humans offered more solutions. Through STEM fish were managed by building ladders for them to move up the dammed river, fish hatcheries that raised and released juvenile fish to increase salmon stock production, and fish cultivation to satisfy increased demand. The solutions, perceived from a particular stance, positioned STEM *over* place where humans took control *over* the river, the salmon, and the entire ecosystem.

Styres’ framework for Indigenous thought: philosophies of land

Kanien’kehá:ka Mohawk scholar Sandra Styres (2017) offers a storied circular framework “about the ways Indigenous philosophies are formed and informed by connections to land and understandings of self-in-relationship” (p. 19) in her book *Pathways for Remembering and Recognizing Indigenous Thought in Education: Philosophies of Iethi’nihsténha Ohwentsia’kékha (Land)*. Concepts of circularity through what Styres refers to as the elements Vision, Relationships, Knowledge, and Action, animate how Indigenous philosophies and pedagogies come from and are informed by relationships with land, language use, and self. The framework offers us opportunities for lively discussions that embody circularity with which to (re)think connections to land, opportunities for what Stó:lō scholar Q’um Q’um Xiiem Jo-ann Archibald (2008) refers to as Indigenous storywork, and reflections on our own (re)forming relationships with land including with human and more-than-human (Abram, 1996) worlds. Styres’ dynamic, generative, and fluid framework enables each element to be in relation to the collective whole. The unifying concepts of circularity and recursivity emphasize Archibald’s (2008) emergent Indigenous storywork principles of synergy, inter-relatedness, and holism. In this section of the paper we introduce, and then use, Styres’ framework to examine and articulate examples of imagining STEM *with* and *as* place/land.

Vision-(re)centering

The smoke is the place of visioning—where we imagine what is or could be possible, where we identify and articulate the importance of doing this work, why now—here—in this time. Visioning opens opportunities for deep and profound insight and introspection as we explore and examine the ways we engage with the natural, spiritual, and built worlds.

Styres (2017, p. 5).

Land, in Styres' framework is more than a physical and geographic place, land is "mother earth", a sentient being that both cares for us and requires care from us. Land in this sense includes waterways, oceans, sky, urban and rural areas, the animate and inanimate, and the human and more-than-human. Okanagan poet and scholar Jeannette Armstrong (1998) writes of the life force of land that "holds all knowledge of life and death and is a constant teacher ... the land constantly speaks. It is constantly communicating" (p. 176). According to Armstrong it is this understanding of land that brings forth languages where, not only do the vocal sounds parallel the rhythm and movement of mother earth, they also engender respect and recognition of co-dependency and reciprocity for survival. This connectedness is dynamic and reinforced through the spoken word of the language and stories. In this way, the land speaks and thus has (educational) agency.

Other worldviews, such as settler colonial perspectives, envision nature, place/land as a resource to be named, used, and exploited (Bowers, 2016). These colonial spaces are, note Larsen and Johnson (2017), created by displacing and possessing in acts of oppression that reject and ignore peoples' (human and non) relationships with land. Colonial conceptions of place and land, privilege land as serving pathways for human agency, where land is understood as a backdrop to, even a stage for, human activity such as STEM.

Land as a backdrop for STEM activities involves what Skovsmose (1994) calls mathematical formatting--where mathematics participates in creating our world. For instance, mathematical modeling formats our responses and decisions through what can be measured, predicted and controlled. A measurable way of knowing the world, indeed a STEM literacy way of knowing the world, does not typically include our ancestors' stories, or what Styres (2017) calls very old pedagogies, or what ecophilosopher David Abram (2011) calls the "sensory craft of listening and the sensuous art of storytelling" about local and direct experiences in a particular place (p. 16). Consider again the Columbia River. Viewing STEM from the perspective as using place, the consequences of damming the Columbia River, including displacing lives and disrupting relationships *with* place/land, are seen as minimizing costs for maximizing human and economic gains.

Visioning and re(centering) STEM education to include an eco-critical focus is also found in the works of Wolfmeyer, Lupinacci and colleagues (e.g., Wolfmeyer et al., 2018). Drawing upon ecojustice education frameworks, these authors examine possibilities for STEM education that emphasize the inseparability of environmental and social justice issues. Like ecological philosopher Plumwood (2014) and ecojustice theorist Bowers (2016), Wolfmeyer and colleagues challenge the human/nature dualism that assumes humans as possessing higher consciousness and thus agency over nature. The authors argue that such assumptions enable the further rationalizing of humans as exceptional, separating the rest of the world as non-human (animals, forests, rivers, oceans, air, etc), and reducing them as mere resources, tools or slaves with which to serve human needs. As an example, Wolfmeyer et al. (2018) offer the story of incarceration as a possible critical STEM project to engage students in questioning the role and consequences of this human/nonhuman divide. Their project highlights the inhumane practices that human confinement embed through the physical imprisonment and incarceration (slavery) of nonhuman animals through agriculture (e.g., dairy farms), experimentation (e.g., research on animals), and human entertainment (e.g., zoos and aquariums). This leads us to ask: In what ways can we (re) vision and (re)center STEM education so we may see ourselves as part of ecosystems rather than as exceptional beings separate from nature? And in doing so, how do these ways then allow us to attend to the interests of humans and the more-than-human worlds (Kimmerer, 2013)?

Returning to the river

Consider the harnessing power of the Columbia River running through BC, Canada and the two American states of Washington and Oregon. Recognized as the fourth largest North American river (by volume), the Columbia runs across more than 2000 km of land, dropping through rocky canyons and high mountain ranges before meeting the Pacific Ocean in Oregon (Northwest Power and Conservation Council, 2020a). In one year, the river moves an average of 192 million acre-feet of water to its mouth (an acre-foot is an engineering term to describe the volume of water covering one acre one-foot deep). The river's power, length, and flow, create a home for fish and other plants and animals/wildlife. For Indigenous peoples the river sustained a way of life, language and culture. Salmon and salmon fishing provided economic, ceremonial, and nutritional benefits as well as forms of cultural practices. For colonial settlers, the river, predominantly held potential for agriculture irrigation and hydroelectric power, resources necessary to respond to the growing industrial and consumer demands of the two countries.

Between 1933 and 1941 the Grand Coulee Dam was built on the Columbia River in Washington state to address flooding issues along the river, as well as the need for irrigation, less expensive power generation, and job creation during the Great Depression. The Grand Coulee Dam is a massive structure, considered at the time as one of the largest concrete structures in the world, and known by some as the world's Eighth Wonder (McClung, 2009). Forming a lake 243 km long behind it, the Grand Coulee created a spillway of 393 m discharging about 1,000,000 L of water per second (Northwest Power and Conservation Council, 2020a). The dam represents a human STEM triumph designed to transform the river's current, gravity flow, and power into electricity and irrigation. But at what cost to place/land?

Relationships-(re)membering

To envision other possibilities for STEM, possibilities that decenter human's asymmetrical use of place for STEM, we return to Styres' circular framework and the next element of Relationships and (Re)membering. For Styres (2017) (re)membering involves the "ways one is able to bring forward into the present a conscious awareness of past events, individuals, and knowledges ..." (p. 43). A new calling to mind of "new dynamic ways to (re)member our relationships to Land" (p. 43).

Indigenous perspectives emphasize the significance of place as acknowledged in its power to shape experiences, language and culture (Deloria and Wildcat, 2001). Place shapes us and defines us. Relational and embodied, place imbues the complex interconnections that make humans, "as much a part of the land as any other element" (Coulthard, 2010, p. 80). This view aligns with what Tewa biologist Greg Cajete (2004) calls natural democracy--an interdependence of humans "with plants, animals, stones, water, and everything else" (p. 46). Moreover, that land is alive with stories and our teacher (Abram, 2011; Simpson, 2017; Styres, 2017). Contrast this with a more colonial understanding and experiencing of place. For example, place known and lived as an abstract geometric position rather than an intimate experience of dwelling (Abram, 2011) enables objectifying, separating, and privileging
